TABLE OF CONTENTS, VOL. III.

PART I. THE MAMMALIA OF SOUTHERN PATAGONIA.

By J. A. ALLEN.

PART II. BATRACHIANS AND REPTILES.

By LEONHARD STEJNEGER.

PART III. THE FRESH-WATER FISHES OF PATAGONIA AND AN EXAMINATION OF THE ARCHIPLATA-ARCHHELENIS THEORY.

By CARL H. EIGENMANN.

PART IV. CATALOGUE OF THE FRESH-WATER FISHES OF TROPICAL AND SOUTH TEMPERATE AMERICA.

By CARL H. EIGENMANN.

PART V. NON-MARINE MOLLUSCA OF PATAGONIA.

BY HENRY A. PILSBRY.

PART VI. CRUSTACEA OF SOUTHERN PATAGONIA.

BY A. E. ORTMANN.

DATES OF PUBLICATION OF THE PARTS OF VOLUME III.

The dates of issue, as printed on the inside of the covers of the various parts, are approximations made in advance and in each case antedate the time of actual issue to the subscribers. These dates should therefore be corrected as follows:

Pp. 1–210, Pll. I–XXIX, published May 4, 1905.

Pp. 211–374, Pll. XXX–XXXVII, published July 3, 1909.

Pp. 375–511 published March 11, 1910.

Pp. 513–687, Pll. XXXVIII–L, published July 20, 1911.

PART V.

PART I.

MAMMALIA OF SOUTHERN PATAGONIA.

BY

J. A. ALLEN,

AMERICAN MUSEUM OF NATURAL HISTORY, NEW YORK.

INTRODUCTION.

THE area covered by the present report includes that portion of Argentina situated south of south latitude 40°, Tierra del Fuego, and the southern part of the Chilian Territory of Magellan, or that portion of it lying west of Tierra del Fuego. The main Andean chain thus forms the western boundary. Its basis is primarily the collections made by the Princeton Expeditions, gathered mainly in the Territory of Santa Cruz, to which material it was intended at first to restrict the report. Later it seemed desirable to extend the scope to include what seems to be a fairly well marked faunal region. Finally, to impart to it something of the character of a monograph, and perhaps thus add to its usefulness, it was decided to include not only full bibliographical references, but also, in most instances, descriptions of the species, and such accounts of their life histories as could be conveniently brought together, including especially the field notes of the collectors.

The Princeton Expedition's collections of mammals were made partly on the coast, and partly in the interior at the eastern base of the Andes, by O. A. Peterson in 1897, and Mr. E. A. Colburn in 1898, and aggregate about 600 specimens. A few specimens collected by Mr. Barnum Brown in 1899, and by him presented to the American Museum of Natural History, and various specimens belonging to the U. S. National Museum have also been utilized, while great assistance has been derived from the examination of the material from this and adjoining parts of South America in the British Museum.

Mr. Peterson's collection[1] numbers about 370 specimens, of which 134 —70 large mammals, and 64 small mammals—were taken along the coast, at different points from the Rio Gallegos to the Rio Coy, from May 13 to November 29, of which the greater part were collected in July and August, and are thus in midwinter pelage. They include a large series of the Guanaco and Gray Fox, and about 64 Rodents of various species. The remaining, and by far the larger part of the collection (about 240 specimens), was made on the headwaters of the Rio Chico de Santa Cruz, at the eastern base of and in the Cordilleras, including a few from the Pacific Slope. These embrace a small series of the Chilian Deer or Guamul, the rest being Rodents, which number nearly 20 species. The Cordilleras collection was made January 31 to March 6, and hence consists of midsummer to early fall specimens, and they are thus not satisfactorily comparable with the coast series. The coast series, however, fortunately contains, in several instances, summer and winter specimens of the same species, showing the quite different pelages of the two seasons. The Peterson collection was purchased by Dr. C. Hart Merriam for the Biological Survey, and now forms part of the collection of the U. S. National Museum.

Mr. Colburn's collection consists of about 200 specimens, of which 18, representing five species, were taken at Punta Arenas during the first week in January; and 10 were taken near Port Desire (labelled "Mount Observation"), February 21–23, and represent three species. Then followed a continuous journey of some 250 miles up the Rio Chico de Santa Cruz, to the mouth of the Rio Belgrado, during which no specimens of mammals appear to have been collected, and only a few (about 25) were taken on the way north from the Rio Belgrado to the vicinity of Lake Buenos Aires.[2] During the month of April work was prosecuted con-

[1] While Mr. Peterson was charged with the collecting of the recent material, it should be noted that Mr. Hatcher at all times coöperated with him in the work, and that many of the specimens were collected by him. (See Hatcher, Narrative of the Expedition, pp. 62, 65, 138, 144.)

[2] Most of the specimens are labelled "Arroyo Eche" (= Aike) a locality not indicated on maps nor even mentioned in Mr. Hatcher's Narrative of the expedition, but which he has kindly located for me as covering the Basalt Cañons and Swan Lake localities, the dates on the labels indicating to which they refer. While Mr. Colburn's specimens are well made, and are accompanied by measurements, indication of sex and date of collecting, he informs me that he "took no field notes." Besides this, about one third of the skulls are unavailable for study, owing either to their actual loss or to the loss of their labels, or to illegibility of the labels due to soiling from lack of care in the preservation of the skulls.

tinuously at camps in the Basalt Cañons, a pampa country having an altitude of about 3,000 feet. A few specimens were collected near Swan Lake, some fifty miles to the southward, in March, but none were taken after May 15, during the return journey to the coast. Hence nearly all of the 200 specimens collected by Mr. Colburn were taken in March, April, and the first half of May, or during the season corresponding to fall in northern latitudes, and in the elevated pampa country, at the eastern base of the Andes, between the mouth of Rio Belgrado and Lake Buenos Aires. This collection is the property of the Princeton University, except a series of the duplicates which has been presented to the American Museum of Natural History.

The coast material is especially important as containing practically topotypes of a number of Waterhouse's species of Muridæ, based on specimens collected by Darwin during the voyage of the "Beagle." The sub-Andean series represents a wholly new field, and, as might be expected, contains forms allied, on the one hand, to species previously known only from Tierra del Fuego, and on the other, to species described from Mendoza, nearly a thousand miles to the northward. A number of these prove to be new, though not widely different, respectively from their northern or southern allies.

In attempting to work up this material — the first collection of mammals of any magnitude ever received in this country from Patagonia — it was recognized at the outset that it would be of the utmost importance to make direct comparison of the species represented in it with the types and other authentic material from the same general region contained (almost exclusively) in the British Museum, in which are the types of Bennett's and Waterhouse's species, described more than a half century ago, and the types of Thomas's more recently described species from northern Argentina and Paraguay. Accordingly a good series of specimens was taken to London during the summer of 1901, and through the kindness and cordial assistance of Mr. Oldfield Thomas, Curator of Mammals at the British Museum, I was able to make the necessary critical comparisons with the historic material relating to South American Mammalogy contained in this great Museum. Following the custom of earlier days, the Bennett and Waterhouse types were exhibited for many years as mounted specimens, and thus through long exposure to light suffered much deterioration, but they are still, of course, invaluable as standards of reference.

In the present report only such species are included as have been definitely recorded from within the geographical limits of the region here under consideration. Possibly a few already recorded have been overlooked. However that may be, doubtless many described from points further north will be found to extend into it, and probably some, not here included, described from the coast district of southern Chili, will be found to extend southward and eastward into Patagonia.

As very few of the species of this region have been adequately figured, as regards the skull and dentition, advantage is taken of the present opportunity to publish illustrations of the cranial and dental characters of a considerable number of species, particularly among the Rodents, to serve as standards of comparison in considering allied forms.

As regards the general facies of the Patagonian land mammal fauna, the paucity of types is noteworthy, due to the high southern latitude of the region. It is of course far beyond the range of monkeys and marsupials, while bats, of one or two species, barely reach its northern border. The families Leporidæ, Dasyproctidæ, and Sciuridæ are absent, and the Ruminants are represented by the Guanaco, this region being its metropolis, and by a single species of deer. The Mustelidæ are represented by three genera, *Conepatus*, *Lyncodon*, and *Lutra*, while the Canidæ and Felidæ have each several species. A single species of Armadillo is found as far south as the Rio Santa Cruz. There are two representatives of the Caviidæ, and the family Chinchillidæ is represented by one of its three genera. The abundant genus *Ctenomys* alone represents the Octodontidæ; but the region may be said to be the headquarters of the Murine genera *Reithrodon* and *Euneomys*. Its other characteristic genera of Muridæ are *Akodon*, *Oxymycterus*, *Phyllotis*, and *Eligmodontia*, while the wide ranging genus *Oryzomys* has here a few outlying species. The only murine genus peculiar to the region is *Notiomys*, known thus far by a single specimen taken near Santa Cruz, nearly twenty years ago, by the French Mission Scientifique du Cap Horn.

The shores and outlying islands of Patagonia were formerly great resorts of antarctic types of Pinnipedia, representatives of which still exist, but in greatly reduced numbers, including of the Otariidæ, the genera *Otaria* and *Arctocephalus*, and of the Phocidæ the genera *Mirounga*, *Hydrurgus*, *Leptonychotes* and *Lobodon*.

During the preparation of this work several new forms have been dis-

covered among the Rodents, and several changes of nomenclature in other groups proved imperative, and have been made known in advance of the publication of the completed work. The following papers have therefore been the outgrowth of the present undertaking.[1]

In this connection my thanks are especially due to Dr. C. Hart Merriam, who kindly turned over to me the whole of the Peterson Collection of Mammals for elaboration; to Professor W. B. Scott of Princeton University, at whose solicitation this work was undertaken, for superintending the preparation of a large part of the drawings for the illustrations here presented, and for seconding in every way my efforts to secure a satisfactory presentation of the results of my work; to Mr. J. B. Hatcher for an early transcript of his field notes (since published in his narrative, to which they are herein duly credited); to Mr. Barnum Brown, who accompanied the Princeton Patagonian Expedition of 1899, for important field notes, a few specimens, and much verbal information about the country;

to Mr. Oldfield Thomas, of the British Museum, for free access to the collections under his charge, and for much valuable assistance.

Subclass EDENTATA.

Order DASYPODA.

Of the Edentates, so numerously represented in tropical America, only the Armadillos reach Patagonia, and of these only a single species is represented in the collections made by the Princeton University Expeditions; and this finds its southern limit of distribution at the Rio Santa Cruz. A second species of Armadillo, *Tatu hybridus* (*Dasypus hybridus* Desm.), is recorded from northern Patagonia, and is said to extend as far south as to the Rio Negro, which region, however, is outside of the geographic limits assigned to the present report.

Not only are the Sloths (Bradypodidæ) and the Anteaters (Myrmecophagidæ) absent from the existing fauna of Patagonia, but, according to Professor Scott, no trace of them has yet been found in the Santa Cruz beds, in which Armadillos are represented in such great abundance and diversity. This seems to show, as stated by Scott, that the true Sloths and Anteaters "must have originated in some other part of the South American Continent and were prevented by climatic or other barriers from extending their range into Patagonia."[1]

The majority of the Armadillos of the Santa Cruz beds "belong to extinct lines," which for the most part "are not known to pass beyond the limits of the Santa Cruz formation." To quote from Professor Scott (*l. c.*, p. 8) in respect to the relationship of the extinct to the modern forms, he says:

"Attention has already been called to the difference between the Santa Cruz and the recent Armadillos, a difference which can be made clear in a few words. No probable forerunner of *Dasypus*, *Priodontes*, *Tolypeutes*, *Chlamydophorus*, or *Tatu*, has been found in these beds, though some one of the species of *Prozaëdius* was almost certainly an ancestor of the recent *Zaëdyus*, and it is possible, though far from certain, that some species of *Stenotatus* stood in the same relation to the modern *Cabassous*. In view of the stage of differentiation attained by the Santa Cruz Arma-

[1] Reports Princeton University Exped. Patagonia, Vol. V, Part I, 1903, p. 4.

dillos, it is most improbable that all these modern types should have originated since that period. This confirms the conclusion indicated by several other mammalian series, that in Miocene times Patagonia was not the principal theatre of evolution of the South American fauna. This would explain the entire absence from the Santa Cruz beds of many types which would naturally be expected to occur there."

Family *DASYPODIDÆ*.

Genus ZAËDYUS Ameghino.

Dasypus (*Euphractos*) *minutus* Burmeister, Reise durch die La Plata-Staaten, II, 1861, 427.

Euphractus minutus Gray, P. Z. S., 1865, 377, fig. skull.
Dasypus (Tatusia) minutus Burmeister, Desc. phys. Rép. Argent., III, 1879, 440.
Zaëdyus minutus, Ameghino, Contr. al Conoc. Mam. fós. Rep. Argent., 1889, 867.
Tatusia hybrida Hatcher, Narrative Patagonian Exped., I, 1903, 116. Habits and distribution.

General color of cephalic shield and carapace dark brown, irregularly varied with lighter, the lateral edges of both areas much lighter, pale yellow or whitish, particularly the lateral row of plates on the carapace; tail yellowish, mottled with darker; posterior edge of dorsal plates thickly set with very short fine blackish hairs, interspersed with long yellowish brown and whitish bristles, 40 to 50 mm. long, thinly veiling the carapace; below thickly clothed with long rather coarse hairs, yellowish white on the ventral surface, brownish on the shoulders and thighs; sides of head thickly covered with fine short dark brown hairs, forming a broad lateral band.

Measurements.—Adult male, total length, 395 mm.; tail, 140; hind foot, 63; ear (in dry skin), 14. Adult female, total length, 390; tail, 120; hind foot, 60. Skull, total length, 68–70; zygomatic breadth, 39–42; mastoid breadth, 35–37.

Represented by 6 specimens (two immature), collected by Mr. Colburn near Swan Lake, March 5 and 6, and by one specimen collected by Mr. Barnum Brown, near the junction of the Rio Chico and the Rio Santa Cruz.

This species, like other Armadillos, varies greatly in cranial characters with age, as shown by the three skulls figured on Plate III, where Fig. 1–1*b* represents the skull of an animal about half grown; Fig. 2–2*b*, a skull of a much older animal, and apparently full grown to judge by the appearance of the skull; Fig. 3–3*b* represents the skull of a very old individual, the skull being much larger, very heavily ossified, and disproportionately broader than either of the others. Compared with full-grown middle-aged specimens, it differs from the latter so strikingly that, without intermediate specimens, it might readily be mistaken for a different species.

According to Mr. Hatcher's observations, the Rio Santa Cruz forms the southern boundary of the range of the species, whence it extends northward to Paraguay and northern Argentina.

Mr. Hatcher in referring to the animal life of the country bordering the lower Rio Chalia, chronicles (Narrative, pp. 116, 117) his first meeting

with this little Armadillo (erroneously here called *Tatusia hybrida*), and gives the following important imformation about its distribution and habits in southern Patagonia:

"In addition to all these and many other birds and mammals, which had been our daily companions ever since our arrival in Patagonia, there was one curious little mammal belonging to an entirely different order, representatives of which we had not met with south of the Santa Cruz River. I refer to the little Armadillo, *Tatusia hybrida*. Frequent examples of these were to be seen running about over the pampa or lying prone upon the ground. Immediately on touching one of these little animals, they roll themselves up into a compact ball in much the same manner as do some of the leeches or species of chitons, on being detached from the stones to the surface of which they are usually fixed. When in this position the bony covering of the carapace serves to protect them from their ordinary enemies. They live in shallow holes excavated in the surface of the pampa, and if by any chance they succeed in reaching the mouth of one of these before being captured, they force the serrated edges of the carapace into the surrounding dirt in such manner that they can be extracted only with the greatest difficulty. At this latitude they hibernate in winter and prefer a warm sandy soil and sheltered locality. In such places they are fairly abundant north of the Santa Cruz River, but we never observed a specimen south of that stream, nor after careful enquiries could I discover that they had ever been seen by others in the region lying south of this river. It seems probable, therefore, that this stream has afforded an effective barrier to their further distribution to the southward, for not only are there many localities to the south that would seem quite as well adapted to their needs as those to the north, but the entire southern half of the valley of that river is especially well suited to them. Though common in the valley on the north side of the river, no example has ever been taken to my knowledge in the valley on the south side. The temperature of the water in this stream, its great size, and the absolutely treeless nature of the entire region through which it flows renders it particularly capable of presenting an effective barrier to the free migration of certain mammals, and more especially those like *Tatusia,* which are probably not capable of swimming and are known to hibernate in winter, at which period alone they would be able to cross such a stream on the ice. Their flesh is of an excellent flavor and highly prized by the natives as food."

Mr. Prichard confirms Hatcher's statement regarding the absence of this animal south of the Rio Santa Cruz. He found it "very common in the vicinity of Bahia Camerones." He further says: "I saw no specimen in the forests of the Andes, but near Lake Buenos Aires and Lake Viedma we found them about the foothills" (*l. c.*, p. 258).

Order UNGULATA.

The Ungulates are represented in the existing fauna of southern Patagonia by two species only, the Guanaco, belonging to the Camelidæ, and the Guamul, a Cervid.

Family *CERVIDÆ*.

The Deer of Patagonia constitutes a peculiar type restricted to the southern Andean region. Although it has only recently become well known, it has a peculiarly interesting literary history, as shown below.

Genus HIPPOCAMELUS Leuckart.

Hippocamelus Leuckart, De Equo bisulco Molinæ, 1816, 23. Type, *Hippocamelus dubius* = *Equus bisulcus* Molina. — Thomas, P. Z. S., 1898, 212. — T. S. Palmer, Science (2), X, No. 249, Oct. 6, 1899, 494; Index Gen. Mamm., 1904, 326.

Cervequus Lesson, Nouv. Tabl. Règne Anim., 1842, 173. Type and only species, *Equus bisulcus* Molina.

Furcifer Wagner, Schreber's Säug. Suppl., IV, 1844, 384. Type and only species, *Cervus antisiensis* Pucheran = *Equus bisulcus* Molina. — Gray, P. Z. S., 1850, 236.

Xenelaphus Gray, P. Z. S., 1869, 498. Type, *Xenelaphus huamel*, sp. nov. = *Equus bisulcus* Molina (♂ with malformed antlers).

Anomalocera Gray, Scientific Opinion, Oct. 6, 1869, 385. (*Cf.* Philippi, Arch. f. Naturg., 1870, i, 46.)

Huamela Gray, Ann. and Mag. Nat. Hist. (4), X, Dec. 1872, 445 (in text); *ibid.*, XI, March, 1873, 217. Type, *Huamela leucotis* (Gray) = *Equus bisulcus* Molina.

Creagoceros Fitzinger, Sitzb. Akad. Wien, LXVIII, 1873, 358. Includes *Cervus antisiensis* D'Orbigny, and *Cervus chilensis* Gay & Gervais.

In 1782, Molina, as is well known, mentioned and gave names to a large number of the mammals of Chili, describing some of them in suffi-

cient detail for their easy recognition, and others more vaguely, so that their identification is more difficult. Among the latter is the "Guemul," or "Huemul," which he named technically *Equus bisulcus*. He certainly could not have been familiar with the animal, and probably described it from hearsay information, comparing it with the horse and ass, and in no way making any suggestion of its relation to the deer tribe. In fact he gives no character that is in any way distinctive of the animal. Yet, apparently mainly on the basis of its vernacular name, the animal is now universally conceded to be the species first properly introduced into scientific literature by Gay and Gervais in 1846 under the name *Cervus chilensis*, which they recognized as "le Guamul des Chiliens," and also as the *Equus bisulcus* of Molina. In the meantime Molina's animal had been introduced into the works of the earlier systematists as a species of *Equus*, and as late as 1827 was recorded as a species of *Auchenia* on the basis of Molina's account. In 1803 it became the subject of a Latin dissertation by Leuckart, who made it the basis of his genus *Hippocamelus*, substituting at the same time the specific name *dubius* (*Hippocamelus dubius*) for Molina's name *bisulcus*.

Mr. Lydekker, in his "Deer of All Lands," has adopted, as have Dr. Matschie and others, the name *bisulcus* Molina for the species, but he rejects *Hippocamelus*, as also the later *Cervequus* Lesson, "on account of their inappropriate nature," for the later *Xenelaphus* Gray. This statement amounts to the concession that the "inappropriateness" of the name *Hippocamelus* is the only objection to its adoption, which is without weight under the rule that names are not to be rejected "because of barbarous origin, for faulty construction, for inapplicability of meaning, or for erroneous construction" (A. O. U. Code, Canon XXXI). It must therefore be adopted for the Guamul group of deer, as stated by Mr. Thomas in 1898 and by Dr. T. S. Palmer in 1899.

Hippocamelus bisulcus (Molina).

(Plates IV, V, and VI, Skull.)

Equus bisulcus Molina, Sagg. Stor. Nat. Chile, 1782, 320.—Gmelin, Syst. Nat., I, 1788, 209 (ex Molina).—Fischer, Syn. Mam., 1829, 433 (ex Molina).

Cervus bisulcus Matschie, Ergeb. Hamb. Magalh. Sammelreise, III, 1898, 19. Reinstates Molina's name *bisulcus*.

Mazama bisulca Lydekker, Deer of All Lands, 1898, 296; P. Z. S., 1899, 917, pl. lxi, animal, and head, text cut. Patagonia.—Berg, Comunic. Mus. nac. de Buenos Aires, I, No. 7, Oct. 1900, 260–263 (full synonymy).

Hippocamelus bisulcus Thomas, P. Z. S., 1898, 212, Chubut, East Patagonia.

Form stout and heavy. Antlers small, with a single fork near the base, the front tine less than half as large as the main branch, both nearly vertical in direction.

Winter Pelage. — General color of body above and limbs grizzled yellowish brown; the hairs individually are ashy for about the basal two thirds, then pass gradually into blackish, with a narrow subapical band of pale yellowish brown, and a minute black tip, resulting in a grizzled yellowish gray-brown general effect; flanks and ventral surfaces similar, except that the median abdominal area is suffused with blackish; black facial pattern Y-shaped, the arms of the Y beginning over each eye and uniting on the median line somewhat in front of the eyes and passing forward as a rather sharply defined band to the end of the nose, where it spreads laterally to the sides of the lower jaw, thus forming a black cross-band a little behind the muzzle; a broad, light-colored eye-ring; lachrymal pit and eyelids blackish; cheeks and sides of neck lighter and grayer than the body; ears well clothed, grayish externally, varied with pale yellowish brown, white internally; tail above and on the sides like the back, lower surface white; inguinal region white, passing into pale yellowish brown on the inside of the thighs; inner side of fore legs near the body light yellowish brown; tarsal glandular tuft close to the tarsal joint, the anterior upper two thirds whitish, the lower part dusky passing posteriorly into rusty brown.

Measurements. — Two adult males, respectively, total length 1575 mm. and 1727; girth at chest, 965 and 1143. Adult female, total length, 1549; girth at chest, 1143. The following measurements are from an adult mounted male in the American Museum of Natural History (No. 13558), collected by Mr. Peterson at the eastern base of the Cordilleras, at the head of the Rio Chico de Santa Cruz, February 18, 1897: Total length, following the curves of the body, 1750; tail vertebræ, 120; hind foot, 425; height at shoulders, 930; ear from crown, 200; from notch,

170; main tine of antler from burr, 260; short tine from burr, 165; main tine from fork, 180; short tine from fork, 95.

Male skull, adult but not old: Total length, 295; basal length, 260; zygomatic breadth, 107; greatest orbital width, 115; greatest occipital breadth, 88; distance between base of antlers at the skull surface, 52; length of nasals, 100; greatest breadth of nasals, 30; palatal length, 174; anterior palatal foramina (each), 37 × 10; width of palate at m^3, 41; length of upper tooth row, 86; length of lower jaw, inner base of incisors to posterior border of condyle, 217; height at condyle, 96; lower premolar-molar series, 89; diastema, 67; Antlers: length of main tine from burr, 225; length of anterior tine from burr, 178; length of main tine from fork, 166; of anterior from fork, 113; length of bony pedical, 17.

Represented by 5 specimens, 4 males and 1 female, collected at the eastern base of the Cordilleras at the head of the Rio Chico de Santa Cruz, February 10–18 and March 1, 1897, by Messrs. Peterson and Hatcher.

The Patagonian Guamul differs from the Peruvian Guamul (*Hippocamelus antisiensis*) in smaller size, stouter antlers, with the anterior tine relatively smaller, and the point of bifurcation a little further up from the burr, and the facial black markings less extended posteriorly. In general coloration, and doubtless in habits, the two species have a close general resemblance.

The Patagonian animal has been repeatedly described and figured, a recent excellent colored figure of it having been published by Lydekker (Proc. Zoöl. Soc. London, 1899, pl. lxi), together with a good text cut of the head (*l. c.*, p. 918). Prichard (*l. c.*) has also recently given a good figure of the animal in summer coat.

The group of Guamul deer presents a case of unusually complicated synonymy, which, however, has been carefully sifted and straightened out, first by Sclater and later by Matschie, Lydekker, and Berg, by whose labors I have greatly profited in the present connection. On the rather unsatisfactory principle of exclusion, and the vernacular name used by Molina, the three last named authors have seen proper to employ Molina's specific designation *bisulcus* for the present species, the adoption of which seems unfortunately necessary under the rule of priority, there being of course no reasonable doubt as to what animal Molina so vaguely indicated under this name.

As shown by the following field notes, contributed by Mr. Brown, and

the excerpts from Mr. Hatcher's "Narrative," the range of this species in Patagonia is confined to the immediate vicinity of the Cordilleras. Mr. Brown, in referring to this species, says:

"No deer are to be found on the plains, but one species is fairly abundant in the mountains. It is about the size of the Virginia deer; the males armed with a pair of two-pronged antlers. I killed two and saw many, but only the one species. Unlike the guanaco that have never seen man, these deer are very tame, allowing one to approach within a few yards of them." (Barnum Brown, MSS. notes.)

Mr. Hatcher, in writing of the region to the east and southeast of Lake Buenos Aires, thus refers to the deer:

"While nowhere in the plains region of Patagonia had we seen the Chilian deer, *Cariacus chilensis*, yet I was not greatly surprised to encounter it here in a region which, though destitute of forests and distant from fifty to one hundred and twenty-five miles from the Andes, had all the characteristics of a rugged mountainous region, when one descended from the narrow, flat-topped tablelands to the bottoms of the cañons. I not only met with deer on various occasions in these cañons, but on returning to camp after this my first protracted journey in this region, as I was traveling up the chasm in which we had pitched our tent, I came suddenly upon a band of three at a distance of hardly more than half a mile from camp. Since we had thought of remaining where we were for the winter, this seemed an excellent opportunity for providing an ample supply of jerked venison, which is far superior to the flesh of the guanaco." (Hatcher, *l. c.*, p. 185.)

His first meeting with this animal, however, was in the primeval forests at the base of the Andes, some distance to the southwest near Mayer Basin. He says:

"After a few hours spent in a vain search for mammalian remains in these beds I started for camp, returning by way of the forest through which I had passed on my way thither. Just as I was emerging from the wooded tract into the meadow land in front, I came suddenly and unexpectedly upon three deer browsing quietly in the grass along the margin of the wood. They were the first I had seen in Patagonia, and for a moment it was evident that I was the most startled individual of the four. They made no effort to escape, as they might easily have done by taking to the wood, but stood at a distance of not more than twenty

feet, returning my expression of surprise with one of interested curiosity. For an instant I stood admiring the rich golden brown of their sleek, glossy coats, as they alternately cropped the rosebuds and other choice morsels from the foliage about them, or cast inquiring glances toward me. Suddenly, remembering that we had been without fresh meat for breakfast, I deliberately, though reluctantly, drew my revolver from its scabbard, and having for a moment subdued the compassionate feeling with which I had been seized, it required little skill to despatch one of the trio and demonstrate that man is not less brutal than other animals. Indeed, from a certain, and to my mind questionable standpoint, it was about as unsportsmanlike an act as could have been committed. But, like others even more unsportsmanlike which I shall later have occasion to relate, it served the double purpose of providing us with a supply of meat and an addition to our collection of the skins of recent Mammalia. The two companions remained, unalarmed either by the report of the fatal shot, or the death struggles of their companion. While engaged in skinning and dressing the carcass of the dead animal, the live ones stood at a distance of only a few yards, either indifferent, or at most only curious as to the nature of the operation, and I could at any moment have easily despatched them, had I been so inclined. Covering the carcass and skin with brush so as to protect them from the caranchas, I returned to camp, and, saddling a horse, conveyed both to our tent, where they were properly cared for." (Hatcher, *l. c.*, pp. 130, 131.)

The following forcibly illustrates the tameness of these animals in their native haunts:

"In the early morning and late afternoon deer were common about the edges of the wood and in the small open parks within, while in the middle of the day they were frequently met with in the depths of the forests. The degree of confidence and fearlessness displayed by these traditionally timid animals was indeed most remarkable. It was plainly evident that they were entirely unacquainted with man. On one occasion, while tramping through the woods with my shotgun in quest of smaller game, I came upon a full grown male lying quietly at the base of a large tree. As I stopped to observe him, he remained quite still for a moment and looked at me, with nothing of fright in his countenance. Then slowly getting upon his feet he came walking directly toward me with that measured and firm tread characteristic of the family. The entire attitude and bear-

ing of the animal resembled that of a favorite cow or horse, as, lazily basking in the barnyard, it rises and advances slowly to lick the proffered hand of its master. I permitted this exhibition of confidence to continue until he had approached to some ten or twelve feet of me, when I showed my unworthiness by exchanging a charge of small for one of solid shot, which, after backing away for a few paces I discharged with such effect that the beautiful animal fell lifeless almost at my feet, a victim of misplaced confidence." (Hatcher, *l. c.*, pp. 137, 138.)

Mr. Hatcher makes further reference to their tameness, as observed in Mayer Basin, on page 200 of his "Narrative," and again on page 266, when they would approach to within a few feet while he and Mr. Peterson were "skinning and dressing the carcass of their fallen comrade, often approaching so near that we would be compelled to suspend operations and urge the spectators to remove to a more respectful distance."

Mr. Prichard's account of this deer is very full and quite in harmony with the observations of Mr. Hatcher and Mr. Brown, already given, including its tameness, geographical distribution, and general habits. Mr. Prichard says they shed their winter coat in December. He gives a colored plate of the animal in summer coat, and good half-tone illustrations of the skull. When he first published his account of the species little had been made public concerning its habits and distribution. (See *l. c.*, especially pp. 248–251.)

Family *CAMELIDÆ*.

Genus LAMA Cuvier.

Camelus Linn. Syst. Nat. ed. 10, 1758, 65 (in part).

Lama Frisch, Natur-Syst. vierfüss. Thiere, 1775 (*apud* Palmer, Index Gen. Mamm., 1904, 363, 921). — G. Cuvier, Tabl. Élém. Hist. Nat. Anim., 1798, 158 (= "les Lamas"); Leçons d'Anat. Comp., I, tab. 1, 1800. — Desmarest, Nouv. Dict. d'Hist. Nat., XXIV, 1804, Tabl. mèth. 31. — G. Fischer, Zoognosia, III, 1814, 351. — Gray, Cat. Mamm. Br. Mus., III, Ungulata Furcipeda, 1852, 254. — Thomas, P. Z. S., 1891, 385.

Lacma Tiedemann, Zool., I, 1808, 420 (= *Lama* G. Cuvier, 1798).

Auchenia Illiger, Prod. Syst. Nat., 1811, 103 (*Lama* G. Cuvier; also preoccupied for a genus of Coleoptera). — G. Cuvier, Règne Anim., I, 1817, 251. — Wagner, Schreber's Säug., V, ii, 1838, 1788.

Dromedarius Wagler, Natürl. Syst. der Amphib., 1830, 31 (to replace *Auchenia* Illiger, preoccupied).

The name *Lama* (Frisch, 1775; G. Cuvier, 1798) has priority over the, for a long time, more current name *Auchenia* (Illiger, 1811), and should be adopted for the genus, as long since shown by Thomas (*l. c.*). Of the four forms of these animals commonly recognized, the Guanaco, Llama, Alpaca, and Vicuña, only the first comes within the scope of the present work.

Opinions differ as to whether these animals are to be treated as distinct species, or whether they are all to be considered as races of a single species. Mr. Thomas (*l. c.*) has given his reasons for considering the Vicuña as a distinct species, and the Llama and Alpaca as merely domesticated races of the Guanaco, thus recognizing two species.

Lama glama huanacus (Molina).

Camelus glama Linn. Syst. Nat. ed. 10, 1758, 65 (in part — based on the domesticated race). — Shaw, Gen. Zoöl., II, ii, 1801, 241, pl. clxviii.

Mamm., 1898, 846; Prichard, Through Heart of Patagonia, 1902, 104–107 (Indian method of hunting), 138–140 (hunting), 156 (head of young), 160 (pl., "descending a hillside"), 236–239 (habits), 253–257 (habits, etc., side view of head); P. Z. S., 1902, I, 275.

Auchenia lama, b. *guanaco* Wagner, Schreber's Säug., V, ii, 1836, 1803, 1806–1810, pl. cccv *a*.

Auchenia llama Waterhouse, Zoöl. Voy. Beagle, Mamm. ii, 1839, 26 (with notes on habits and distribution by Darwin).

Auchenia lama Brandt, Mém. Acad. Imp. St. Pétersb., IV, 1845, 1, pl. i, ii. — Cassin, U. S. Expl. Exp. (Wilkes), Mamm. and Orn., 1858, 65 (Rio Negro; Tierra del Fuego). — Burmeister, Desc. phys. Rép. Argent., III, 1879, 457.

Camelus guanaco Traile, Mem. Wern. Nat. Hist. Soc., IV, 1823, 492, pl.
Auchenia guanaco Meyen, Nov. Ac. Acad. Leopold.-Cæs., XVI, 1833, 552, pl. lx.
Lama guanaco Gay, Hist. Chili, Zool., I, 1847, 153.
Lama guanacus Gray, Cat. Mamm. Br. Mus., Ungul. Furcip., 1852, 257, pl. xxiv, fig. 2, skull.
Guanaco, Cunningham, Nat. Hist. Strait Magellan, 1871, 106–109 (habits). — Hatcher, Rep. Princeton Univ. Exped. Patagonia, I, pp. 58, 62, 271, and elsewhere *passim* (habits and distribution).

In winter pelage the general color above is reddish brown, darkening a little on the rump and tail, this being the color of the long over hair, beneath which is a dense, matted covering of short woolly under fur, of much lighter color; flanks and ventral surface white; head all around and ears gray, lighter or paler on the throat and sides of the face, and darker, dusky gray on the whole front and top of the head; edges and tips of the ears and the muzzle whitish; fore limbs externally like the dorsal surface as far as the "knees," then dark grayish brown to the hoofs, more or less mottled with rufous; hind limbs externally rufous as far as the callosity, the grayish passing into rufous on the metatarsus and toes; inside of both fore and hind limbs white, like the ventral surface.

Young a few weeks old are similar in general coloration and markings to the adults except that the upper parts are lighter rufous and the under parts clearer white.

A large series of specimens (about 20) of this species was taken by Messrs. Peterson and Hatcher, chiefly in the vicinity of the coast near Cape Fairweather, but only a small part of them have passed through my hands. Mr. Peterson's measurements show that adults range in total length from about 1950 to 2150 mm., with a girth of about 1270, and that adult females attain very nearly the same dimensions.

Much has been published on the habits of the Guanaco, as observed in different parts of its range, by different writers, especially by Darwin, Cunningham, Hudson, and Prichard, but a transcript of Mr. Hatcher's observations, with a few additional notes by Mr. Barnum Brown, do not appear to be out of place in the present connection. Mr. Brown's manuscript notes are as follows:

"The Guanaco, which is by far the most numerous of the large mammals, ranges from Grandi Island, about 100 miles north of Cape Horn, over all

of Patagonia that I have traversed; that is north to 46° N., from the Andes to the coast.

"Although there are a good many Guanacos on Tierra del Fuego, and a few on the other small islands, Lenox and Grandi, the extremely moist climate, with its consequent peculiarities of vegetation, principally mosses and lichens, does not seem suited to it. . . .

"Contrary to Mr. Darwin, I should not call this an elegant animal. It seems ill-proportioned and awkward, especially when running, when the body seemingly has two separate motions, reminding one of a hobby-horse with a movable neck. The Guanaco has but two movements, the walk and the gallop. When galloping both hind legs are moved together, a fact which makes it necessary for the Indians to throw their bola so as to catch a hind and a fore leg, as a bola tied around the hind legs in no way retards the forward movement.

"Near settlements, along the coast and rivers where they frequently see men, the Guanaco is quite easily approached, being seemingly not afraid of man, but merely curious. I have often been within fifty yards of them. In fencing in the large estancias great numbers are often enclosed, where they may be seen feeding contentedly with the sheep. In the Andes and on the high pampas, however, where they never see man, one rarely gets closer than three or four hundred yards; more often only a hideous, mirage-distorted figure is seen as they disappear in the distance. Here they are as wild as our western Pronghorn.

"During the summer months they feed singly and in small groups scattered over the pampas; rarely more than a dozen are found together. But during the winter months, as the snow gradually covers the grass on the pampas, they range toward the sea coast and rivers, and feed in large herds in the barancas or broken coast where the sea breezes melt the snow. From one hill in the Rincon de Boca, north of Rio Coy, I have counted four herds containing from three hundred to a thousand each.

"While feeding one of the males usually stands guard on higher ground, giving the alarm if an enemy appears. This alarm, the only noise I have heard them make except when fighting or brought to bay, is a prolonged drawn-out neigh.

"While camped in an old lake bed near the Cordilleras, I was startled one morning by a series of peculiar screams very much like those of a horse in distress. Running to a hill near by I saw two large males fight-

ing. With ears laid back and mouth wide open, one rushed the other, this way and that, now turning, then in a straight run till near enough to cut a gash along his opponent's ribs with his sharp, hooked canines. Furious, the other turns with a scream, and runs after his antagonist till he, too, has scored a mark; and they kept at it over an hour until both were exhausted and badly cut up.

"When bunched during the winter months they feed together and run in close packs after their leaders like sheep. Remarkably fleet and surefooted, they are as agile as the Rocky Mountain Sheep. When the ground was frozen several feet deep, with an inch melted on top, I have seen them, running at full speed, plunge over cliffs two or three hundred feet high at an angle of 75 degrees, where I deemed it too hazardous to attempt descent with the aid of a pick, and never have I seen one come to grief."

As will be seen from Mr. Hatcher's account, this observer does not consider the aid of man necessary to account for the presence of the Guanaco in Tierra del Fuego. The following excerpts are from Mr. Hatcher's "Narrative."

"The Guanaco is, to his [the Tehuelche Indian's] existence, the one important and indispensable animal. From its flesh he derives his chief, and for long periods, only sustenance, while from its skin his industrious wife constructs the family toldo and makes with admirable skill and patience their ample clothing and bedding, fitting and sewing the parts with the nicety and proficiency of a skilled seamstress. A wooden or bone awl, used as a delicate punch, is her needle, and the sinews taken from the loin of the same animal her thread. From this same beast he likewise obtains the sinew for the light but exceedingly strong thongs of his bolas.

"But the Guanacos are in no danger of extermination. They roam in thousands over the Patagonian plains. So abundant are they that, in traveling across the country, it is scarcely possible to pass out of sight of them. Contrary to the rule with undomesticated animals, the Guanacos inhabiting settled regions are far less timid than those of unsettled districts. In the region along the coast occupied by the sheep farmers they exist in great numbers, are exceedingly tame, and are a source of considerable annoyance to the herdsmen, who, nevertheless, suffer them to go unmolested. Beyond the settlements the Guanacos are more difficult of approach and in the Cordilleras they are exceedingly wary, as is also the Rhea, or so-called Ostrich. This is the more striking and difficult of ex-

planation, since the deer in the same mountainous region seem absolutely fearless and are prompted by curiosity rather than fear when approached. . . .

"The Guanaco is not only the largest animal inhabiting Patagonia, but to the Tehuelche, at least, it is surely of the most importance. It is the American representative of the camel and, though readily domesticated, no attempt seems ever to have been made in this region, by either whites or Indians, to bring this species under domestication. There is little doubt, however, that the Llamas and Vicuñas, of Peru, are but domesticated varieties of the Guanaco.

"When full grown, the Guanaco is in size about equal to that of a yearling colt. I have elsewhere described their form, color and peculiar call. They are abundant on the plains, both of the mainland and Tierra del Fuego, having been found even to the southern limits of that island. They are also fairly common in the valleys of the Andes. Their presence in Tierra del Fuego, to which island the rhea, puma and Patagonian deer, *Cariacus chilensis*, have not gained access, is but an illustration of their superior powers of self-distribution. When hard-pressed they readily take to water, and when pursued by a pack of hounds have been known to take to the Gallegos River, at the place where the village now stands, where it has a width of three miles. With their well-known fearlessness of water, there is little wonder that they have been able to reach Tierra del Fuego, since the Magellan Strait, at both the first and second narrows, has a width of only two miles. They have a pecular habit, as remarked by Darwin, of dropping their dung in the same place, so that great accumulations of this are to be seen in piles scattered all over the plains. Some writers, more especially Hudson, have also claimed that the Guanacos of any particular region all resorted to a particular spot to die. My observations in Patagonia did not verify such a conclusion. It is true that I frequently observed a considerable number of Guanaco skeletons in the same immediate locality, but their presence in such places was easily accounted for. During the winter storms these animals would be driven from the surrounding plains to seek shelter in the river valleys and there, beneath embankments or clumps of bushes, would be found the remains of such as, through old age or disease, were unable to survive the rigors of the storm they had sought to escape. The abundance of Guanaco skeletons in such places is no more remarkable, and is, in fact, due to the same

circumstances that have caused the presence of several skeletons of domestic cattle or, in earlier days, of buffalo, in similar places all over our western plains." (Hatcher, *l. c.*, pp. 266 and 271.)

Mr. Prichard has also given recently a very full account of the Guanaco (*l. c.*, pp. 253–287, and *passim*) adding many details of interest respecting its habits, and an account of the Indian and other methods of hunting it.

Order GLIRES.

Exclusive of the great family Muridæ, only four genera of Rodents are represented in southern Patagonia, namely, *Kerodon* and *Dolichotis* (family Caviidæ), *Viscaccia* (family Chinchillidæ), and *Ctenomys* (family Octodontidæ). The first three are each represented by a single species, but *Ctenomys* numbers at least four within the area here under consideration. They are all characteristic types of the pampas of Patagonia, Argentina, and southern Bolivia. Even northern Patagonia is quite beyond the range of Hares, Squirrels, Porcupines, and even of the large Rats of the genus *Nectomys*, and of the Spiny Rats so characteristic of southern Brazil and Paraguay.

The abundance of Rodents is a striking feature of the Patagonian fauna. Mr. Barnum Brown, who spent several months in 1899 in Tierra del Fuego, and traversed large portions of the island in his geological explorations, says (MSS. notes):

"Rodents are very abundant, especially in the valleys and along the foot-hills where the entire earth over large areas is completely undermined. In the northern part of Tierra del Fuego it is difficult to ride through the campos on account of these burrows."

Mr. Hatcher refers to the great numbers of these animals on the upper Rio Chico. In connection with his notice of the Burrowing Owl and the Short-eared Owl (Narrative, p. 121) he says: "And indeed there seemed no limit to this source of their food supply, for not only was the surface of the ground literally covered in many places with the well-used trails of these small mammals, which crossed in every conceivable direction, but in many places the earth beneath the surface was honeycombed to the depth of a foot or more with their subterranean burrows, in such manner that our horses sank at each step half way to their knees and the wheels of our cart plowed great ruts in the surface of the ground."

Again, at the moraine near the junction of the Rio Belgrano with the Rio Chico, he says (Narrative, p. 123): "The side of the slope, as well as the little plain at its foot, was literally alive with rodents." And then follows a more detailed account (pp. 124, 125) of the species observed, in which special reference is made to the Kerodon and the Tuco-tuco (*Ctenomys*), quoted in full under these species, and to various unidentified species of mice, as follows:

"In the small brush which grew at the base and over the slopes of the bluff above our camp, there lived a variety of small rodents for the most part characterized by large, thin ears, delicate soft fur of a bluish brown color above and lighter on the belly, with tails of various length, which in some species might be described as short and in others much attenuated.

"The tall grass which covered the river valley swarmed with myriads of small rodents somewhat larger than those just mentioned, with usually smaller ears, smaller tails, and a coarser pelage of an almost uniformly dull brown color. While these little animals were present in the greatest abundance they seemed all to pertain to one of two or three different species and exhibited very little variety of either form, size or color."

A heavy rainstorm made evident the fact that these little animals, especially the burrowing species, are quite an effective geological agent in producing erosion, and also that they suffer at times great destruction from the elements. On these points he says (p. 125):

"On walking about the following morning I was much impressed, not only with the amount of erosion which had been effected by the storm, but with the great destruction to animal life of which it had been the cause. Proceeding along the foot of the bluff, I observed a number of dead bodies of the little *Ctenomys magellanica* lying about upon the surface, and could only guess at the number of carcasses of these and other rodents that were buried beneath the débris, that during the night had been washed down from the bluff above and now lay at my feet, covering no inconsiderable portion of the surface of the valley to a depth varying from an inch to one or two feet. While the dead bodies of rodents belonging to other species were not wanting, the storm appeared to have been especially destructive to the little tuco-tuco, owing no doubt to the peculiar habit of that animal in burrowing so near the surface of the ground in search of food. When erosion on the surface had made an opening in the burrow at any point, a torrent of water would rush into the subterranean channel, either instantly

drowning such of its inhabitants as were caught below, or driving them to seek refuge by escaping from the burrow where they were certain to meet with a similar death from the downpour of rain on the outside. As I walked about this morning considering the destruction wrought by the storm of the previous night, I was struck with the great importance of the work accomplished by rodents and other burrowing animals, when considered as agents of erosion, and it appeared to me that this source of erosion had not been given sufficient attention in our text books of geology, when treating of the various erosive agents."

Family *CAVIIDÆ*.

Kerodon australis (Is. Geoffroy).

(Plate VII, Fig. 1, Skull.)

Cavia australis Is. Geoffroy-St. Hilaire, Guérin's Mag. de Zool., 1833, Cl. I, pl. xii, animal. Northern Patagonia. — D'Orbigny, Voy. dans l'Amer. Mérid. Mamm., 26, pl. xviii, figs. 1–4. — Thomas, P. Z. S., 1898, 211. Chubut, E. Patagonia. — Hatcher, Narrative Princeton Univ. Patagonian Exped., I, 1903, 123, habits.

Cavia (*Cerodon*) *australis* Waterhouse, Mamm., II, 1848, 180, pl. iii, fig. 2, animal, pl. xvi, fig. 13, skull from below.

Cavia [*Aneoma*] *australis* Burmeister, Descrip. phys. Rép. Argent., III, 1879, 272.

Kerodon kingii Bennett, P. Z. S., 1835, 90, Port Desire, Patagonia. — Waterhouse, Zoöl. Voy. Beagle, Mamm., 1839, 88. — Trouessart, Cat. Mamm., ii, 1897, 639.

Adult (March–May). — Above dark yellowish gray, finely varied with black; sides lighter, less varied with black-tipped hairs; ventral surface white with a slight yellowish tone, varied more or less with gray, through the showing more or less at the surface of the dull gray underfur; sides of nose, a narrow eye ring, and the space between the eye and ear yellowish gray, or buffy white, with a postauricular patch of pale buff; ears thinly clothed, the very short hairs yellowish gray on both surfaces; upper surface of feet pale yellowish gray, the toes lighter, clear pale buff; toe pads and callosities blackish.

Young. — Scarcely at all different from the adults, and, like the adults, different specimens vary from yellowish white to mottled grayish white below.

Adults vary individually in the amount of yellowish suffusion above, some being quite strongly yellowish, while others are dark gray with very little tinge of yellow.

Measurements.—Eight adult and semiadult males measure as follows: Total length, 217.5 mm. (210–230); hind foot, 50 (49–52). Eight adult and semiadult females: Total length, 218.8 (210–230); hind foot, 48.5 (47–52). The skulls show that few of the specimens of which the measurements are here given are full grown. No. 84180, a male, is the only very old individual, with the skull heavily ossified, in the series. This specimen has a total length of 230, and the length of the hind foot is 52. The skull of this specimen measures: Total length, 54; zygomatic breadth, 32; interorbital breadth, 10.5; greatest width of brain case, 25; mastoid breadth, 22; length of nasals, 19; palatal length, 24; palatal foramina, 7.4; diastema, 13; upper molar series, 13.5; lower jaw, length from inner base of incisors to posterior border of condyle, 36; do., to end of angular process, 42; height at condyle, 14; lower molar series, 13.5.

The next oldest skull is that of a female, No. 84182, which has the same external measurements as the male, namely, total length, 230, hind foot, 52. The skull, however, is considerably smaller, measuring as follows: Total length, 47; zygomatic breadth, 29; least interorbital breadth, 10; greatest width of brain case, 21; mastoid breadth, 15; palatal length, 20; palatal foramina, 5.3; diastema, 10.8; upper molar series, 11.2; lower jaw, length from inner base of incisors to posterior border of condyle, 31; do., to end of angular process, 35; height at condyle, 12; lower molar series, 11.3.

Represented by 29 specimens, of which 20 were collected by Mr. Colburn near Swan Lake and the Basaltic Cañons, in March and April, and the remaining 9 by Mr. Peterson, on the upper Rio Chico de Santa Cruz, in the valley close to the river, near the Cordilleras, during the month of February. Thus the pelage of only one season is represented.

This animal evidently continues to increase in size for a long period. Of the 29 specimens in the present collection only one or two, or at most three, appear to have reached fully adult conditions, and these do not show indications of old age. In this respect they resemble the Geomyidæ among North American Rodents, and the *Didelphis* group among Marsupials.

Charles Darwin's notes on the habits and distribution of this animal, as published by Waterhouse in "Zoölogy of the Voyage of the Beagle," are

still worth quoting, and constitute nearly all that has been heretofore published on the subject. He says: "The Kerodon is common at intervals along the coast of Patagonia, from the Rio Negro (Lat. 41°) to the Strait of Magellan. It is very tame, and commonly feeds by day; it is said to bring forth two young ones at a birth. At the Rio Negro it frequents in great numbers the bottoms of old hedges; at Port Desire it lives beneath the ruins of the old Spanish buildings. One old male killed there weighed 3530 grains. At the Strait of Magellan, I have seen amongst the Patagonian Indians, cloaks for small children made with the skins of this little animal; and the Jesuit Falkner says, that the people of one of the southern tribes, take their name from the number of these animals which inhabit their country. The Spaniards and half-civilized Indians, call the Kerodon, 'conejos,' or rabbit; and thus the mistake has arisen, that rabbits are found in the neighborhood of the Strait of Magellan." — Darwin, Voyage of the Beagle, Mamm., pp. 88, 89.

Mr. Durnford (*cf.* Thomas, *l. c.*, p. 212), writes of its presence at Chubut, as follow: "Extremely abundant, and found in every clump of brushwood throughout the neighborhood. This little animal is very good eating. It sits up like a rabbit on its hind-quarters while chewing the mouthful it has just taken."

Mr. Hatcher (Narrative, p. 123) refers to their abundance at the junction of the Rio Belgrano and Rio Chico as follows: "Hopping about among the bushes and rocks were to be seen in great numbers representatives of the little gray, tailless and hare-like *Cavia australis.* Most interesting and amusing little creatures they are, as, always alert and intent on detecting the first approach of danger, they hop about from one position to another, or sit erect on their haunches and nibble unceasingly at a fragment of plantain leaf, or other morsel of food held conveniently in the fore paws. The favorite haunts of these little animals are shallow burrows about the bases of the larger bushes, or beneath certain herbaceous plants like *Bolax glabaria,* that grow in broad, dense, cæspitose masses upon the surface of the ground."

This little animal thus appears to be abundant over a wide extent of territory, in the foothills of the eastern base of the Andes as well as along the coast, and probably at all favorable localities throughout the intervening districts.

Genus DOLICHOTIS Desmarest.

Dolichotis Desmarest, Journ. Phys., LXXXVIII, 1819, 205; Mamm., II, 1822, 359, 360, footnote. Type *Dasyprocta patachonica* Desmarest = *Cavia patachonica* Shaw = *Cavia magellanica* Kerr (1792).

Mara Lesson, Cent. Zool., 1832, 113. Type, *Cavia patachonica* Shaw.

DOLICHOTIS MAGELLANICA (Kerr).

Hare Narborough, Voyage to Magellan, 1694, 33; also 1711, 33.

Patagonian Cavy Pennant, Hist. Quad., II, 1781, 363, pl. xxxix; 2d ed., II, 1793, 91, pl. xci. Based on Narborough's account and specimens. Port Desire, Patagonia.

Cavia magellanica Kerr, An. King, 1792, No. 454.

Dolichotis magellanica Thomas, Ann. and Mag. Nat. Hist. (5), IV, 1879, 397. Revival of Kerr's name.

Mara magellanica Lesson, Cent. Zool., 1832, 113, pl. xlii. (*Mara patagonica* on the plate.)

Cavia patachonica Shaw, Gen. Zoöl., II, i, 1801, 226, pl. clxv. From Pennant and Narborough; plate from a specimen in Leverian Museum, brought by Narborough from Patagonia. — Waterhouse, Zoöl. Voy. Beagle, Mamm., II, 1839, 89.

Chloromys patagonicus Desmoulins, Dict. class. d'Hist. Nat., IV, 1823, 47. — Lesson, Man. de Mamm., 1827, 301.

Mara patagonica Lesson, Cent. Zool., 1830, pl. xlii.

Dolichotis patachonica Waterhouse, Nat. Hist. Mamm., II, 1848, 158, pl. iii, fig. 1, animal, pl. iv, fig. i, skull. — Cassin, U. S. Expl. Exp. (Wilkes), Mamm. and Orn., 1858, 22, Patagonia.

Dasyprocta patagonium Schinz, Cuvier's Thierreich, IV, 1825, 324.

Chloromys patagonica Lesson, Mamm., 1827, 301.

Dolichotis patagonica Wagner, Schreber's Säug. Suppl., IV, 1844, 66. — Burmeister, Reise durch die La Plata-Staaten, II, 422, habits, external characters and anatomy; Desc. phys. Rép. Argent., III, 1879, 260. — Trouessart, Cat. Mamm., ii, 1897, 641. — Prichard, P. Z. S., 1902, I, 277; Through Heart of Patagonia, 1902, 67, 257, 258 (habits and distribution).

General color above dark gray, passing into black on the lower back and rump, forming a large black patch which extends laterally to the loins; thighs crossed by a broad band of white; ventral surface with a broad median band of yellowish white, occupying the middle of the throat, and the median ventral area from the posterior border of the pectoral region to the tail; pectoral and prepectoral areas dull ochraceous, which color also forms a broad lateral line from the cheeks to the loins, gradually passing into the gray of the upper parts; ears gray, thinly haired, the tips fringed with long rusty brown hairs, and the anterior base fulvous, joining a broad postocular patch of ochraceous brown; a narrow yellowish brown eye-ring, the lids and the long eyelashes black, as are also the whiskers; front and sides of nose pale yellowish; fore limbs externally gray, varied with black, passing into black on the feet; inside of fore limbs ochraceous buff; hind limbs pale yellowish gray proximally, passing first into fawn, and then into yellowish gray on the proximal half of the tarsus, mixed with black on the apical portion, and the toes black; inner surface of hind limbs pale fulvous; toe pads and tarsal callosity black; rest of under surface of hind feet heavily clothed with rusty fulvous hairs.

There are no flesh measurements but a well made skin gives the following: Total length, 620 mm.; tail, 12; hind foot, 143; ear from notch, 63.

The Patagonian Cavy is represented by a single specimen (skin and the complete skeleton), collected by Mr. J. B. Hatcher at the mouth of the Rio Chico, February 10, 1899. He makes, however, no reference to the species in his "Narrative." This locality appears to form its known southern limit of distribution. It is an animal of the arid plains, and its habits have been well described by Darwin and later writers. It lives in burrows, but feeds and roams about by day, wandering, according to Darwin, miles from its burrow, in little parties of two and three, and is shy and watchful. It brings forth two young at a birth, which are produced within the burrow. Its range appears to extend from about latitude 30° to latitude 50° south, wherever the country is favorable to its needs.

The Patagonian Cavy was first formally made known by Pennant in 1781, from a specimen in the Leverian Museum collected by Sir John Narborough near Port Desire, in Patagonia. Sir John refers to it as a "Hare" and says: ". . . they are shaped like English hares, and much larger, and instead of a tail have a little stub about an inch long, without hair on it; they have holes in the ground like Coneys."

Mr. Prichard says it is "called 'cavy' or 'hare' indiscriminately by the English residents; *liebre* by the Argentines and Chilians; *paahi* by the Tehuelches."

Although Mr. Hatcher obtained a specimen at the mouth of the Rio Chico, Mr. Prichard gives the Rio Deseado as the "southern limit of the distribution of the Patagonian Cavy," and adds:

"As far as my experience goes, I never observed a cavy after October 23, upon which day I counted fourteen upon the pampa between Lake Musters and the settlement of Colohuapi. The residents of Colohuapi informed me that the place formed the southern limit of the distribution of the cavy. It is, of course, impossible to lay down an exact line, but I think it safe to say that the range of the cavy does not extend south of the 46th parallel. This limit is the more remarkable inasmuch as the country south of latitude 46° does not in any way materially differ from that over which the cavy is commonly to be met with. One most often finds these animals on patches of dry mud. They are comparatively easy to stalk, as easy as an English rabbit. The best method of shooting them is, of course, with the rifle, though occasionally you may start them from a thicket and shoot them as you would an English hare with a shot-gun. They generally weigh between 18 pounds and 25 pounds, though I heard of one which I was assured weighed 31 pounds." (*L. c.*, p. 257.)

Dolichotis magellanica ranges northward into southern Argentina, and is replaced in the Province of Cordova, central Argentina, by a northern subspecies *Dolichotis magellanica centricola* Thomas, where it occurs with the much smaller *D. salinicola* Burmeister.

Family *CHINCHILLIDÆ.*

The Viscacha of Paraguay and Argentina is the only member of the family Chinchillidæ known to occur in Patagonia, where it is apparently not found to the southward of the Rio Negro, and thus hardly calls for extended notice in the present connection. The genera *Chinchilla* and *Lagidium* are restricted to the Andean region, mainly of Peru and Chili.

Genus VISCACCIA Oken.

Viscacia Rafinesque, Anal. de la Nature, 1815, 56. Nomen nudum.
Viscaccia Oken, Lehrb. d. Naturg., III, 1816, 835. Type, *Lepus chilensis*

Oken = *Dipus maximus* Desmarest (ex Blainville). *Cf.* Allen, Proc. Biol. Soc. Wash., XV, 1902, 196.

Viscaccia Schinz, Cuvier's Thierreich, IV, 1825, 429. Type, *Viscaccia americana* Schinz, sp. nov. = *Dipus maximus* Desmarest (ex Blainville), 1817. *Cf.* Thomas, Proc. Biol. Soc. Wash., XIV, 25, April 2, 1901; Allen, *ibid.*, 181, Dec. 12, 1901.

Vizcacia Schinz, Naturg. und Abbild. der Säug., 1824–1828, 244 (*circa* 1826). Also 2d ed., 1827 = *Viscaccia* Schinz, 1825. — Lahille, Congr. Cien. Lat. Amer., III, 1899, 192. *Cf.* Palmer, Science (2), VI, No. 131, 21, 22, July 2, 1897.

Viscacia Rengger, Naturg. der Säug. Paraguay, 1830, 272, footnote. = *Viscaccia* Schinz, 1825 (= *Viscaccia* Oken, 1816).

Lagostomus Brookes, Trans. Linn. Soc. London, XVI, pt. 1, 1829, 102. Type, *Lagostomus trichodactylus*, sp. nov. = *Dipus maximus* Desmarest, 1817.

As shown by the above synonymy and references, the proper generic name of the Argentine Viscacha has been the subject of considerable discussion; and while Schinz in 1825 adopted for it the name *Viscaccia*, the same name appears to have been used for it nine years earlier by Oken, both uses of the name having the same basis, namely "la Vizcache" of Azara. Later Schinz varied the form of the name to *Vizcacia*.

As stated by me in 1901, the case is as follows: As has been fully shown,[1] there is no doubt of the pertinence of the generic name *Viscaccia* Schinz, 1825, to "la Vizcache" of Azara, the Argentine Viscacha. But it turns out that Oken (Lehrb. d. Naturg., Theil III, Abth. 2, p. 835, 1816) used the same term in 1816, in nearly the same sense. Oken included in his group or subgenus *Viscaccia* only two species: (1) *Lepus chilensis* and (2) *Mus laniger*. The first, notwithstanding the name *chilensis*, is based, as far as the description is concerned, wholly on "la Vizcache" of Azara, while in his diagnosis of the group *Viscaccia* he says "Zehen vorn 4, hinten 3," which would exclude his second species, the *Mus laniger* of Molina, and hence the Chinchilla of Peru. As Bennett, in 1829, made the Chinchilla the type of his genus *Chinchilla*, the Argentine Viscacha becomes by restriction the type and only species of Oken's *Viscaccia*, the authority for which name is thus Oken (1816) instead of Schinz (1825).

[1] *Cf.* Palmer, Science, N. S., VI, p. 21, July 2, 1897; Thomas, Proc. Biol. Soc. Wash., XIV, p. 25, April 2, 1901; Allen, *ibid.*, p. 181, Dec. 2, 1901.

VISCACCIA CHILENSIS (Oken).

Vizcache Azara, Hist. Nat. Quad. Paraguay, II, 1801, 41. Not "La Viscaccia, *Lepus viscacia*," Molina, 1782; nor *Vizcacia viscacica* Rehn, Proc. Biol. Soc. Wash., XIII, 1900, 167; nor *Vizcacia viscacia* Allen, *ibid.*, XIV, 1901, 91.

[*Viscaccia*] *Lepus chilensis* Oken, Lehrb. d. Naturg., III, ii, 1816, 835. Based on the Vizcache of Azara, as above.

Viscaccia chilensis Allen, Proc. Biol. Soc. Wash., XV, Oct. 10, 1902, 196 (ex Oken).

Dipus maximus Desmarest (ex Blainville), Nouv. Dict. d'Hist. Nat., XIII, 1817, 117; Mamm., II, 1822, 212. Based on a living specimen seen in London, which specimen later became the basis of *Lagostomus trichodactylus* Brookes.

Vizcacia maxima Palmer, Science (2), VI, 1897, 21; Lahille, Congr. Cien. Lat. Amer., III, 1899, 192.

Viscacia maxima Berg, Com. Mus. nac. Buenos Aires, I, 1900, 220.

Viscaccia americana Schinz, Cuvier's Thierreich, IV, 1825, 429.

Vizcacia pamparum Schinz, Naturg. und Abbild. Säug., 1824–1828, 244 (*circa* 1826).

Lagostomus trichodactylus Brookes, Trans. Linn. Soc. London, XVI, 1829, 95, pl. ix (= *Dipus maximus* Desm. 1817, having been based on the same specimen).—Wagner, Schreber's Säug. Suppl., III, 1843, 310.—Waterhouse, Mamm., II, 1848, 212.—Hudson, P. Z. S., 1872, 822, 833, habits.—Burmeister, Descrip. phys. Rép. Argent., III, 1879, 247.

Callomys viscacia D'Orbigny & Is. Geoffroy Saint-Hilaire, Ann. des Sci. nat., XXI, 1830, 291, habits and distribution (= *Dipus maximus* Desm.; not *Lepus viscacia* Molina).

Lagostomus viscacha Meyen, Nova Acta Acad. Leopold.-Cæs., XVI, 1833 (1834), 584.

For many years the Argentine Viscache was currently known under the specific name *trichodactylus* (*Lagostomus trichodactylus* Brookes, 1829), but it was later found that *Dipus maximus* Desmarest (ex Blainville), 1817, referred to the same animal, and received acceptance as its proper specific name. But it unfortunately happens that Oken's name *chilensis* (*Lepus chilensis* Oken, 1816) has one year's priority over *maximus* of

Desmarest, both names having practically the same basis, namely, the Vizcacha of Azara. As I have elsewhere shown,[1] the Argentine Viscacha must apparently be called *Viscaccia chilensis* Oken.

This species is unrepresented in the present collection, its range not extending below the Rio Negro (latitude 41° south), and it thus barely reaches the northern border of the region here considered.

It has been so fully described and figured by Brookes, Waterhouse and others, that a detailed account of it seems uncalled for in the present connection. An extended notice of its habits has been given by Darwin, and later by Hudson, as observed by them on the pampas of Buenos Aires.

Family *OCTODONTIDÆ*.

Of the Octodonts only the Octodontinæ reach Patagonia, and of the five commonly recognized existing genera of this subfamily only one, *Ctenomys*, appears to have been found east of the southern Andes. The other four — *Aconæmys, Spalacopus, Abrocoma* and *Octodon* — occur within or on the western slope of the Andes, and are not, as now known, numerously represented in species. *Ctenomys,* on the other hand, is characteristic of the plains and pampas, ranging from Tierra del Fuego northward to southern Brazil and Bolivia, and westward into the base of the Andes. It is a plastic and prolific group, swarming in favorable localities, and readily susceptible to changes of environment. At least some twenty-five named forms are at present tentatively recognized, mostly on rather slight differences of size or color. Although the extreme phases are widely separated, it is probable that so many links still remain in the chain of intergradation that when the group comes to be more effectually known many of the forms now treated as species will be found to merge, and that some of the names stand for very little that is tangible. Several extinct forms have also been distinguished, the group extending back into the Pleistocene, and according to some authorities to the Pliocene.

The family Octodontidæ, as at present constituted, forms a very heterogeneous assemblage, comprising groups that might well be assigned to three distinct families. There is, for example, no close relationship between the *Octodon-Ctenomys* series and the Spiny Rats (*Loncheres-Echimys* series), or of either of these with *Ctenodactylus*. At different times each

[1] Proc. Biol. Soc. Wash., XV., 196, Oct. 10, 1902.

of these groups has been assigned, by different authors, the rank of a family, which disposition of them seems fairly to represent their real degree of affinity. We would thus have the comprehensive group Octodontidæ separated into (1) the true Octodonts, or Octodontidæ proper; (2) the Spiny Rats and their immediate allies, or Echimyidæ; (3) *Ctenodactylus* and allied genera, or Ctenodactylidæ. They are severally quite as distinct as are the commonly recognized families Heteromyidæ and Geomyidæ.

Genus CTENOMYS Blainville.

Ctenomys Blainville, Bull. Soc. Philomat., Paris, April, 1826, 64, pl.; Ann. Sci. Nat., IX, 1826, 102. Type, *Ctenomys brasiliensis* sp. nov., Minas Geraes, Brazil.

The Tuco-tucos, as the species of *Ctenomys* are known locally, represent, through closely similar adaptive modifications, in South America the Pocket Gophers (Geomyidæ) of North America. Both are modified for an almost exclusive life underground, having the same form of body, fossorial feet, degenerate organs of sight and hearing, and the same soft, silky pelage. The Tuco-tucos lack the external cheek-pouches of the Pocket Gophers, and differ from them in certain important cranial characters, although the general form of the skull and the structure of the teeth are similar in both. The form of the zygoma and the position and form of the infraorbital foramen are, however, notably different — features that perhaps warrant their wide dissociation as members respectively of the Hystricomorphs and Myomorphs.

The Tuco-tucos, as already said, are exceedingly prolific, in local forms as well as in individuals, and in favorable localities, as in alluvial or moist soils, their burrows fairly honeycomb the earth over considerable areas, rendering traveling, on foot or with horses, more or less difficult and even dangerous.

CTENOMYS MAGELLANICUS Bennett.

Ctenomys magellanicus Bennett, P. Z. S., 1835, 190. Port Gregory, Strait of Magellan; Trans. Zoöl. Soc. Lond., II, 1841, 84, pl. xvii, animal and skull; same specimen. — Waterhouse, Mamm., II, 1848, 283, pl. viii, skull, pl. ix, fig. 2, animal. Based wholly on Bennett's type specimen. — Burmeister, Descrip. phys. Rép. Argent., III, 1879, 239, ex Bennett and Waterhouse. — Trouessart, Cat. Mamm., ii, 1897,

599, part; only the references to Bennett and Waterhouse. — Thomas, P. Z. S., 1898, 211. Tombo Point, on the coast 60 miles south of mouth of Rio Chubut. — Lahille, Congr. Cien. Lat. Amer., III, 1899, 190.

Ctenomys neglectus Nehring, Zoolog. Anz., XXIII, Oct. 8, 1900, 535, fig. 1, skull. Based on a weathered skull from Patagonia.

Waterhouse's description and measurements of the type (*l. c.*) and then only known specimen of this species, being more concise and explicit than Bennett's, are here presented:

"General tint of the fur ashy grey, faintly suffused with yellow, and on the back brownish; abdomen pale ochreous yellow; tail very pale brown: the fur is moderately long, very soft, and of a deep slate grey colour at the root.

"Inhabits Port Gregory [=Cape Gregory of Bennett and of modern maps], Strait of Magalhaen.

	Inches.	Lines.	[mm.]
"Length from tip of nose to root of tail....	8	0	[203]
Length of tail.....	2	6	[63.5]
Length of fore foot and nails		$10\frac{1}{3}$	[22.1]
Length of longest nail		$2\frac{2}{3}$	[6.7]
Length of hind foot and nails	1	$3\frac{1}{2}$	[33]"

A nearly complete skull, and several others more or less incomplete (all weathered skulls — Nos. 23410–23413, U. S. Nat. Mus.), collected by Mr. Charles H. Townsend near Punta Arenas, Patagonia, during the cruise of the *Albatross* in 1887–1888, undoubtedly represent this species, to which I also refer a single specimen (No. 17444, Am. Mus.), skin and skull, and an additional younger skull (No. 17445, Am. Mus.) collected by Mr. Barnum Brown "30 miles south of the Port of Santa Cruz, on the coast" of Patagonia, and by him presented to the American Museum of Natural History. They agree well with Bennett's and Waterhouse's descriptions, and the younger skull agrees with their figure of the skull of the type, even in size. The other, a much older skull, is considerably larger. Mr. Brown's specimens came from about 150 miles north of the type locality and appear to be strictly referable to this species, which differs from the form inhabiting the Cordilleras at the head of the Rio Chico de Santa Cruz, presently to be described, in its very much paler colors, both above and below, but appears not to be distinguishable in cranial characters. It is a pale form, like the later described *Ctenomys fueginus* Philippi from Tierra del Fuego.

The original basis of *Ctenomys magellanicus* was a single specimen collected by Captain King at Cape (or Port) Gregory, on the northern side of the Strait of Magellan, and hence on the mainland of Patagonia. This specimen was considered by King to be "rather a young one," "from the size of the jaw, as compared with the abundant remains of this little animal which are scattered over the surface of the ground" (Trans. Zoöl. Soc. Lond., II, 1841, p. 85); and the skull, as figured by Bennett and Waterhouse, seems to bear out this conclusion, all of the sutures being shown to be very distinct, as in a young animal.

As late as 1848, Waterhouse stated (Mamm., II, p. 283) that, so far as he knew, but one specimen of this species of *Ctenomys* had been brought to Europe; and to this day little has been added to our knowledge of its range or habits beyond the three or four lines respecting the latter contributed by Captain King, namely: "The little animal is very timid; feeds upon grass, and is eaten by the Patagonian Indians. It dwells in holes, which it burrows, in the ground: and, from the number of holes, it would appear to be very abundant. It inhabits the east entrance of the Strait of Magelhaens at Cape Gregory and the vicinity."

In comparing this species with the other species of the genus then known, Waterhouse assumed that its small size was not due to immaturity, "all the teeth being fully developed." As shown, however, by the large series of an allied species in the present collection, the skull more than doubles in size (in bulk, not in linear dimensions) after "the teeth are fully developed"; and furthermore, that his specimen was really quite young, and probably also a female, as indicated by the straightness of the zygomatic arches.

In this connection, as bearing upon the comment on *Ctenomys neglectus* which here follows, it is worth while to note the unlikeness of Bennett's and Waterhouse's figures of the same skull, especially in respect to the position and direction of the fronto-parietal sutures, which are correctly drawn in Bennett's figure, and very erroneously represented in that published by Waterhouse.

In 1900 Dr. Nehring published (*l. c.*) as new a *Ctenomys neglectus* based on a Patagonian weathered skull, of which he gives a figure. He compares this skull with Bennett's figure of the skull of *C. magellanicus*, and is able to distinguish numerous differences between them, which appear to him weighty enough to warrant his treating this skull as the basis of a

new species. His most important character is the presence of a deep, longitudinal sulcus on the upper side of the jugal. It is true that this is not shown in Bennett's figure, which is only slightly shaded, being mainly in outline; but I find this same sulcus is present, in a more or less marked manner, according to the age and sex of the animal, in all of my large series of the genus *Ctenomys* from Patagonia, which includes over fifty skulls, representing several more or less closely related forms. I have, therefore, no hesitation in regarding Nehring's *C. neglectus* as based on an adult female skull of one of the larger Patagonian species, in all probability *C. magellanicus*, although no definite locality is given for the specimen.

Ctenomys fueginus Philippi.

Ctenomys fueginus Philippi, Arch. f. Naturg., 1880, i, 276, pl. xiii, skull. Tierra del Fuego.—Lahille, Congr. Cien. Lat. Amer., III, 1899, 190.

Above mixed yellow and gray varied with black, the basal two thirds of the pelage blackish, with a subterminal band of white or light yellow, and the tips black; ventral surface white, the basal half of the pelage black and the apical half white; tail well clothed with soft hairs, above blackish, especially towards the tip, below clear yellowish white.

Measurements. — Head and body, 227 mm.; tail, 46 (= total length, 273); fore foot to end of claws, 26; longest fore claw, 10; hind foot, 35; longest hind claw, 6. Skull: total length, 49; zygomatic breadth, 28.5; mastoid breadth, 26. (Based on Philippi, *l. c.*)

This species was founded on specimens collected by Lieutenant Serrano of the Chilian Navy in the summer of 1878–79, on "der östlichen Insel des Feuerlandes," and was described and the skull figured by Professor Philippi in 1880 (*l. c.*).

In general appearance he found it not very different from the other species of the genus; his comparison of it, however, with *C. magellanicus* was made, in the absence of specimens, with Waterhouse's description and figure. He found the dimensions of the skull somewhat larger in *C. fueginus* than in *C. magellanicus*, and the zygoma outwardly more convex, as shown by his comparative figures of the skulls of the two species (*l. c.*, pl. xiii). But these differences are not necessarily important, since they are found in allied species to characterize the two sexes of the same species. Other coördinated differences are noted, so that he felt fully warranted in treating the Tierra del Fuego animal as distinct.

His description of the color of *C. fueginus* indicates a pale, ashy gray animal very different from that inhabiting the Cordilleras, but quite similar to *C. magellanicus*, the type locality of which is Cape Gregory, on the northern side of the Strait of Magellan. In view of its insular habitat, and in the absence of proper material for comparison, it seems best to give the species provisional recognition.

Ctenomys robustus Allen.

(Plate VII, Figs. 2 and 3, Skull.)

Ctenomys robustus Allen, Bull. Am. Mus. Nat. Hist., XIX, 185, May 9, 1903. Rio Chico de Santa Cruz, near the Cordilleras, Patagonia.

Pelage soft, short, somewhat lustrous. Above deep yellowish brown, varied with blackish, the hairs being dark slaty plumbeous for the basal two thirds, with a subterminal band of dark rusty yellow, and a very short black tip, with longer blackish-tipped hairs sparsely intermixed; below deep brownish ochraceous; ears dusky brown, barely projecting above the fur; upper surface of fore and hind feet dingy yellowish gray; tail well clothed with fine soft hairs, forming a slight pencil at the tip, yellowish gray, dusky at the tip above.

Other specimens vary from the above in being a little lighter or a little darker, both above and below. Tail variable in color, often wholly without any dusky median line above or any dusky tip; generally there is a very narrow median dusky line, extending from the tip anteriorly for a part or the whole of the length of the tail; in a few specimens it is strongly developed, broadens and increases in blackness towards the tip, and in rare cases the whole tip is black, with a short black stripe on the lower surface of the apical fourth or third of the tail.

Young examples differ from the adults in the general tint being duller and the pelage less lustrous.

Measurements.—Type: Total length, 290 mm.; tail vertebræ, 73; hind foot, 40. Nine adult males measure as follows: Total length, 303.5 (290–322; only one above 310, and only two above 298); tail vertebræ, 81.5 (73–88); hind foot, 40.5 (40–42). Five adult females; Total length, 275 (256–300; only one above 280); tail vertebræ, 75 (70–80); hind foot, 37 (35–40).

Skull, type: Total length, 52.5; basal length, 47; zygomatic breadth, 30; interorbital breadth, 10; mastoid breadth, 29.5; length of nasals, 20;

palatal length, 25; diastema, 16; upper molar series, 9.6; lower jaw, inner base of incisors to posterior border of condyle, 33; inner base of incisors to tip of angular process, 41; height at condyle, 16; lower molar series, 10.3; distance between condyles, 18; distance between tips of angular processes, 37. Ten adult male skulls: Total length, 53.6 (51–55); zygomatic breadth, 30.5 (29–33). Five adult female skulls: Total length, 48 (46–50); zygomatic breadth, 27.5 (26.2–28.6). The mastoid breadth is practically the same as the zygomatic breadth, varying in different specimens from slightly more to slightly less. The greater part of the skulls in the present series are middle-aged, with all the sutures distinct; only two or three give evidence of being very old.

Represented by 23 specimens, all from the upper Rio Chico, Cordilleras, and all collected by Mr. Peterson, February 7 to 28, and one March 6. All but three are in adult pelage, and these have nearly acquired it, only the lower part of the back and rump retaining the pelage characteristic of immaturity. The general color above of the adults varies from strong yellowish brown to slightly rufescent brown, and below from deep ochraceous buff to brownish ochraceous. The color of the tail is very variable, as already noted; except in the case of a few which have the tail practically uniform yellowish gray, no two have the tail colored alike, in respect to the median dorsal line, which varies from a slight trace of dusky to a well defined blackish median stripe, the black widening and increasing in intensity apically; in three specimens the whole tip of the tail is black, including the under surface, two of which are males and the other a female. A few other specimens approach this condition.

As shown by the measurements already given, the females are very much smaller than the males.

The skull is very variable in respect to size and many details of structure, but especially in the size and form of the interparietal. In one specimen it is almost obsolete, forming a mere line less than a millimeter in antero-posterior extent and 5 mm. in transverse extent. Generally it is subtriangular, with a transverse width of 5–7 mm., and an antero-posterior length of 2–4 mm. It is sometimes divided medially into two halves. On each side of the interparietal, and separated from it by the posterior extension of the parietals, is an intercalated bone of variable size and of an irregularly oval front outline, each generally considerably larger in area than the interparietal.

Ctenomys robustus differs markedly in coloration from *C. magellanicus*, but not very appreciably, so far as specimens of the latter are available for comparison, in size or cranial characters. *C. magellanicus* is pale yellowish gray, or ash gray with a fulvous tinge, while *C. robustus* is dark yellowish brown. *C. boliviensis* is very much larger and very much darker and redder, having "the general hue bright rufous brown," and the upper surface of the nose, head, and nape blackish. It appears to have no close relationship to any of the described species of *Ctenomys*.

It was met with only in the alluvial river valley of the upper Rio Chico, at the eastern base of the Andes. Mr. Peterson says of this species: "Very abundant, especially along streams. The ground they occupy is all undermined with their passages, which cross one another in all directions. They are seldom seen on the surface and are difficult to trap." (MSS. notes.) Most of the specimens of this species appear to have been taken in Mayer Basin, at the edge of the Cordilleras, since in writing of this region Mr. Hatcher refers incidentally to Mr. Peterson's obtaining here a splendid collection of rodents, "including a fine series of a much larger species of *Ctenomys* than any we had seen in the plains region" (Narrative, p. 138).

Ctenomys sericeus Allen.

(Plate VIII, Figs. 1 and 2, Skull.)

Ctenomys sericeus Allen, Bull. Am. Mus. Nat. Hist., XIX, 187. May 9, 1903. Upper Rio Chico de Santa Cruz, near the Cordilleras, Patagonia.

Ctenomys magellanica Hatcher, Princeton University Exped. Patagonia, I, Narrative, 1903, 124. Not of Bennett.

Pelage short, soft, silky and lustrous. General color above yellowish gray strongly varied with black, the hairs being slaty plumbeous for the basal three fourths, then banded narrowly with pale yellowish brown and tipped with black; flanks and ventral surface buff; sides of nose yellowish brown; top of nose and top of head like median dorsal region, which is darker than the sides; ears very small, blackish; upper surface of feet dingy gray with a slight yellowish cast; tail pale yellowish, with a median dusky stripe along the apical half of the upper surface.

In some specimens there is a tendency to a well-marked darker median dorsal band, extending from the nose to the base of the tail. Several of the specimens are a little darker than the type above described. The tail

stripe varies in distinctness from nearly obsolete to a broad, well-defined black band running the whole length of the tail.

Young in first pelage are grayer with less fulvous, and the pelage is longer, softer, and less firm.

Measurements.—Type: Total length, 208 mm.; tail vertebræ, 62; hind foot, 28. Five adult males: Total length, 200 (195–208); tail vertebræ, 56.6 (51–62); hind foot, 26.2 (25–28). A single adult female measures: Total length, 210; tail vertebræ, 60; hind foot, 27.

Skull, type: Total length, 39; basal length, 35.2; zygomatic breadth, 24; mastoid breadth, 23.5; interorbital breadth, 7; length of nasals, 13; palatal length, 17; diastema, 10; upper molar series, 7.5; lower jaw, inner base of incisors to posterior border of condyle, 26; inner base of incisors to end of angular process, 29.5; height at condyle, 7; width between condyles, 15.3; width between tips of angular processes 25.6; lower molar series, 8. Four adult male skulls: Total length, 36.4 (34.3–39); zygomatic breadth, 21.5 (20–23.6). An old female skull measures, total length, 36; zygomatic breadth, 20.

In several of the skulls the interparietal is entirely absent, and when present is very small. The lateral intercalated bones are present, and are as variable in form as already described in *Cteňomys robustus.*

Represented by 11 specimens, collected by Mr. Peterson in the Cordilleras of the upper Rio Chico de Santa Cruz, in the valley close to the river, Jan. 31 to Feb. 7, 1897. Six are adults and five are young, partly in the juvenile pelage.

This species considerably exceeds in size *Ctenomys pundti* Nehring, and differs from it very markedly in coloration. The total length of the skull of *C. pundti* is given as 31.3 mm., and the zygomatic breadth as 19.5; the same for *C. sericeus* (average specimens) being, respectively, 39 and 21.5 mm. While it agrees practically in size with *C. bergi* Thomas, from the central part of the Province of Cordova, it differs from it in color, being very much darker throughout.

Ctenomys sericeus occurs with the very much larger and very differently colored *C. robustus*, as both were collected on the same days and at the same localities by Mr. Peterson.

He says of this species: "Burrows extensively in the ground, leaving piles of dirt at the surface like pocket gophers (Geomyidæ). They make a drumming noise while sitting in the mouth of the burrows." (MSS. notes.)

Mr. Hatcher gives a somewhat extended account of the Tuco-tuco, which apparently refers mainly to the present species. The locality is the vicinity of the junction of the Rio Belgrano with the Rio Chico. He says (Narrative, pp. 124, 125):

"All about us, and indeed at times from immediately beneath our feet, could be heard the deep, subterranean drummings of the little tuco-tuco, *Ctenomys magellanica*, as engaged with commendable industry, he drove his little tunnel just beneath the surface, ever onward in search of those nutritious roots and succulent tubers upon which he feeds. These little fossorial rodents seemed especially active in the early morning and late afternoon and evening, During these hours, in localities especially favorable to them, they would be constantly heard, though a careful watch throughout our stay in Patagonia, kept at frequent intervals in order to observe their habits above ground, was only rewarded by a momentary glimpse, on one or two occasions, of a solitary individual, as he appeared for an instant at the mouth of a burrow. On one occasion, however, while walking rapidly along, I came suddenly upon one of these little animals in the grass at a distance of several feet from the mouth of his burrow. The manner in which he ran aimlessly about in search of his hole, with the nose close to the surface of the ground, seemed to indicate, not only that he had lost his way and become bewildered by the grass, which, to him, had all the appearances of a great forest, but that he depended quite as much, if not more, upon his sense of smell as that of sight, while endeavoring to regain the abandoned burrow. Hardly had he entered the latter when the frightened condition under which he had been so evidently laboring while above ground, suddenly and completely disappeared, and he stopped long enough to send back a rapid volley of deep, guttural notes, uttered in defiance at the intruder, who, far from having cherished any sinister designs against the little creature, had only been delighted with this opportunity, brief though it was, of observing him above ground. The entire attitude of the little animal was such as to convince me that his surroundings while above ground, aside from my presence, were distinctly uncongenial, and that he was in every respect especially modified and adapted for a subterranean life, a conclusion which I had previously reached upon observing the small eyes, powerful fore-limbs, and feet well adapted for burrowing, and other anatomical characters common to animals of more or less subterranean habits."

CTENOMYS COLBURNI Allen.

(Plate VIII, Figs. 3 and 4, Skull.)

Ctenomys colburni Allen, Bull. Am. Mus. Nat. Hist., XIX, 188, May 9, 1903. Arroyo Aike, in the Basalt Cañons, fifty miles southeast of Lake Buenos Aires, Patagonia.

Similar to *C. sericeus* but larger, much more strongly suffused with fulvous and less varied with black.

Measurements. — Type: Total length, 230 mm.; tail vertebræ, 65; hind foot, 29. Fifteen males measure as follows: Total length 224.5 (210–240, with one at 245 and one at 250); tail vertebræ, 69 (60–75, with two at 80); hind foot, 30 (28–32, and one at 33). Seventeen females: Total length, 213 (200–225); tail vertebræ, 62.2 (60–65); hind foot, 29.5 (29–31).

Skull. — Type, total length, 43; basal length, 39; zygomatic breadth, 25; mastoid breadth, 25; interorbital breadth, 8.5; length of nasals, 14.3; palatal length, 20; diastema, 6; upper molar teeth, 8; lower jaw, inner base of incisors to posterior border of condyles, 28.5; inner base of incisors to point of angular process, 33.5; height at condyle, 8; width between condyles, 16; width between points of angular processes, 27; lower molar teeth, 8.5. Seven old male skulls measure: Total length, 43 (41–45); zygomatic breadth, 24.3 (23.5–25.3) Fifteen old female skulls: Total length, 38 (36–41); zygomatic breadth, 22.2 (21–24).

Represented by 33 specimens — 16 males and 17 females — all adult except 3, and all collected by Mr. Colburn, of which 16 were taken in the basalt cañons, fifty miles southeast of Lake Buenos Aires, April 2 to 26, and the remaining 17 at Swan Lake, April 2 to May 17.

Aside from the young specimens, which are grayer and much less fulvous than the adults, the variation in color consists in some specimens being a little more strongly suffused with yellowish than others, and in the distinctness of the tail stripe, which is often wholly wanting, or present in varying degrees from a faint trace to a broad black stripe.

This species is intermediate in size between *C. sericeus* and *C. mendocina*, being larger than the former, and differing from it in its more strongly fulvous and generally lighter coloration, and from the latter in considerably smaller size and entire absence of any reddish suffusion.

It is of interest to note that this species was not obtained by Mr. Peterson

in the foothills of the Andes, on the upper Rio Chico, where, however, he found a much larger species (*C. robustus*) abundant, and also obtained, in the same region, a small series of a very much smaller species (*C. sericeus*). In all probability *C. colburni* will be found to be a plains or pampa species, while the others occupy the alluvial river valleys in the foothills of the Andes.

Family *MURIDÆ*.

The Murine fauna of southern Patagonia is as strongly characterized by the types that are absent as by those that are present. The Voles, or the great subfamily Microtinæ, are of course absent, as are also all the characteristic North American genera of the Cricetinæ, as *Peromyscus*, *Onychomys*, *Neotoma*, *Reithrodontomys*, and *Sigmodon*, although all extend into tropical America, and all but *Onychomys* even reach the northern border of South America. Another set of genera, as *Rhipidomys*, *Nectomys*, *Holochilus*, and *Tylomys*, which range over a large part of Central and South America, do not reach even the northern border of Patagonia. Of the seven prominent Patagonia genera — *Euneomys*, *Reithrodon*, *Phyllotis*, *Eligmodontia*, *Oxymycterus*, *Oryzomys*, and *Akodon* — only the last two have a wide distribution to the northward, except in the Andean region, where nearly all are highly developed. The single genus *Notiomys* is thus far known only from the original specimen taken near Santa Cruz. It is closely related to *Eligmodontia* and certain forms of *Akodon* (subgenus *Chelymys*), types that abound over the pampean districts of Argentina and Bolivia.

Genus MUS Linnæus.

In America the genus *Mus*, a strictly Old World type, is of course represented only by introduced species, three or four of which have become almost universally dispersed over both continents, and may all occur in Patagonia, although satisfactory evidence of this is at present lacking.

Mus rattus Linn. Black Rat.

The collection contains a single specimen (a half grown female) collected at Punta Arenas, December 30, 1897, by Mr. E. A. Colburn. The measurements as recorded by the collector are: "Length, 280; tail, 150; hind foot, 32."

In coloration this specimen is very different from the black rats of the

northern United States, being blackish olive gray instead of black, but it can be matched exactly in specimens of corresponding age from Jupiter Inlet, Florida, and from the Island of Trindad, B. W. I., but in both cases these specimens are *Mus rattus* more or less mixed with *M. alexandrinus*, to which category the Punta Arenas specimen doubtless belongs.

The Black Rat (*Mus rattus* Linn.) and the White-bellied or Roof Rat (*Mus alexandrinus* Geoffroy) are widely dispersed in the warmer parts of America, and at many localities hybridize freely, so that specimens of pure strain of either species are rare. In the northeastern United States the Black Rat was formerly an abundant inhabitant of houses and outbuildings in the farming districts, while the Brown or Wharf Rat (*Mus norvegicus* Erxleben = *Mus decumanus* Pallas) swarmed in the cities, particularly about wharves and in warehouses. The latter is not only larger and more powerful than the black rat, but antagonizes it, and has to a large extent driven it out or exterminated it in the New England and Middle States of the Union. In the South Atlantic States the Roof Rat has long been the prevailing species, where it seems to have become widely distributed.

From Mexico, Central America and in northern South America both *M. rattus* and *M. alexandrinus* are often received in collections, being caught in traps, in fields and wooded areas remote from settlements, by collectors in trapping for the indigenous rats of the country. In the Province of Chiriqui, Panama, Mr. J. H. Batty in this way unwittingly collected a very large series of *Mus rattus;* but, as already said, hybrids of *M. rattus* and *M. alexandrinus*, combining in endless variety the characteristics of both species, are widely dispersed in tropical America.

The common House Mouse (*Mus musculus* Linn.), although not represented in the present collection, doubtless also occurs in Patagonia, as it is the most widely dispersed in America of any of the introduced species of *Mus*. Darwin obtained it on East Falkland Island and at Maldonado. It has found its way to subarctic America, in Alaska and the remote interior of northern British Columbia. It is at home, thence southward everywhere, under the widest possible conditions of environment. Almost every collection of small mammals, whether made in the arid regions of our great Southwest, the swampy districts of the Gulf Coast, the hot lowlands of Mexico, Central and South America, or at high altitudes in the Peruvian Andes, contains specimens of this omnipresent pest. It will be

of interest soon to secure large series of specimens from widely separated localities where it has been long established for the purpose of determining what modifications it may have undergone through the influence of very diverse conditions of environment. That strongly-marked differentiation will be obvious is evident from what is already known to have taken place among these mice inhabiting the fields in the vicinity of Jalapa, Mexico, where a well-marked black phase (*Mus musculus jalapæ* All. & Chapm.) has already been developed.[1]

Genus ORYZOMYS Baird.

Oryzomys Baird, Mamm. N. Am., 1858, 458 (as a subgenus of *Hesperomys*). Type and only species, *Mus palustris* Harlan.

Zygodontomys Allen, Bull. Am. Mus. Nat. Hist., IX, 38, pl. i, figs. 1–7, March 11, 1897. Type, *Oryzomys cherriei* Allen. Described as a genus, but more commonly treated as a subgenus of *Oryzomys*.

Oligoryzomys Bangs, Proc. N. Engl. Zoöl. Club, I, 94, Feb. 23, 1900 (as a subgenus of *Oryzomys*). Type, *Oryzomys navus* Bangs.

Erioryzomys Bangs, Proc. N. Engl. Zoöl. Club, I, 96, Feb. 23, 1900 (as a subgenus of *Oryzomys*). Type, *Oryzomys monochromos* Bangs.

Melanomys Thomas, Novitates Zoolog., X, 41 (in text), April, 1903 (as a subgenus of *Oryzomys*). Type, *Oryzomys phæopus* Thomas.

The genus *Oryzomys*, as commonly recognized, is the most abundant and most widely distributed genus of American Muridæ, it ranging from the warmer parts of the southeastern United States to Tierra del Fuego. Altogether about 185 species and subspecies have been referred to it, and the list is still rapidly increasing by the discovery and description of additional forms. Although the group is far from homogenous, the transitions from one type to another are usually by gradual stages. In size the various species range from the size of a house mouse to that of the large brown rat; the tail may be much more than half the total length of the animal or less than one quarter; the supraorbital ridges may be heavily developed or obsolete; and the enamel pattern of the teeth is quite variable. As shown in the synonymy above, several minor groups have been set off as subgenera, with fairly well marked characters, and, owing to the numerical unwieldiness of the genus, it will probably be found convenient, sooner or later, to employ them in the sense of full genera.

[1] *Cf.* Bull. Am. Mus. Nat. Hist., IX, 1897, p. 198.

Only two species, both apparently belonging to the typical section of the genus, are thus far known from Patagonia, where they are restricted to its extreme southern part.

Oryzomys magellanicus (Bennett).

(Plates IX, Fig. 2, Skull; X, Figs. 4 and 5, Teeth.)

Mus magellanicus Bennett, P. Z. S., 1835, 191, Port Famine, Straits of Magellan. — Waterhouse, Zoöl. Voyage Beagle, Mamm., 1839, 47, pl. xiv, animal, pl. xxiv, fig. 6, molar teeth. — Milne-Edwards, Miss. Scient. du Cap Horn, VI, Zool., Mamm., 1890, 20, Orange Bay.

Hesperomys (*Calomys*) *magellanicus* Burmeister, Descr. phys. Rép. Argent., III, 1879, 226 (ex Bennett and Waterhouse).

[*Akodon*] *magellanicus* Trouessart, Cat. Mamm., ii, 1897, 536, ex Bennett and Waterhouse.

? Hesperomys (*Oryzomys*) *longicaudatus* Milne-Edwards, Miss. Scient. du Cap Horn, VI, Zool., Mamm., 1890, 27, pl. iv, fig. 1, animal.[1]

Adult (February). — Above yellowish brown, varied with black-tipped hairs, brighter on the top of the head, and middle and posterior part of the back, and paler on the sides; ventral surface buffy white, varying in different specimens from nearly clear white to strong buff; front of head yellowish gray strongly varied with black; ears of medium size, dusky, very thinly haired; upper surface of feet flesh-color; tail very long, dusky brown, a little darker above than below, and very thinly covered with short, bristly hairs, not concealing the annulations.

Young, one fourth to half grown, in soft woolly pelage, are duller and less suffused with fulvous.

Measurements. — Six adult males: Total length, 216 mm. (202–225); tail vertebræ, 120 (114–125); hind foot, 29.3 (28–30). Adult male skull: Total length, 26; basal length, 21; greatest breadth of brain case, 12; interorbital breadth, 3.6; length of nasals, 9.5; palatal length, 19; diastema, 6; palatal foramina, 5.5; upper molar series, 4.

Represented by 17 specimens, of which 10 are adult and 7 young. They were all, except one, collected by Mr. Peterson in the Cordilleras at the head of the Rio Chico, four (all immature) being marked as from

[1] Mr. Oldfield Thomas, in reply to my inquiry respecting the inclusion of this species by Milne-Edwards, kindly informs me that this was probably an error, and that "the specimens were really *Oryzomys magellanicus*."

the Pacific Slope; they were all taken between February 14 and March 14, 1897. The other specimen is from Punta Arenas, collected by Mr. Colburn, Jan. 1, 1898.

This species has not been previously recorded from north of Orange Bay and Port Famine, the latter being the type locality. The present material extends its known range along the Cordilleras to about latitude 48°.

Oryzomys coppingeri (Thomas).

Hesperomys (*Calomys*) *coppingeri* Thomas, P. Z. S., 1881, 4, figs. 1, 2, ear and foot. Tom Bay, Cockle Cove. — Milne-Edwards, Miss. Scient. du Cap Horn, VI, Zoologie, Mamm., 1890, 26, pl. iv, fig. 2, animal, pl. viii, fig. 2, skull. Orange Bay, Tierra del Fuego.

[*Oryzomys*] *coppingeri* Trouessart, Cat. Mamm., ii, 1897, 529 (ex Thomas and Milne-Edwards).

This species is unrepresented in the present collection. Following is Mr. Thomas's original description of the species, which has since been reported by Milne-Edwards from Orange Bay, southern Tierra del Fuego, where he says the naturalists of the Mission Scientifique du Cap Horn (Mamm., p. 26) found it very common and captured a large number of them.

"Hesperomys (Calomys) coppingeri, sp. nov.

"A skin from Tom Bay, and two specimens in spirit 'caught with trap on a wooded islet about one acre in extent' in Cockle Cove (Feb. 9, 1879).

"Fur very long and soft, fully half an inch in length on the back. Ears rather short, nearly hidden in the fur. Whiskers of medium length, the shorter lower ones forming a thick shining white fringe along the upper lip. On the head and back the wool-hair is of a deep slaty blue for nine tenths of its length; then follows a subterminal band of yellow; and the extreme tip is black. Mixed with this wool-hair there are a considerable number of longer black hairs, the resulting general colour being very similar to that of the common Water-Vole (*Arvicola amphibius,* L.). The dark color of the upper side extends on the limbs to the wrists and ankles, the feet being covered with short shining white hairs. The ears are thickly clothed with short woolly hairs similar in colour to the fur of the back. On the sides the yellow tips of the hairs gradually become lighter, and on the belly they are nearly pure white, the basal portion of the fur, however, from the chin to the anus, still being slate-coloured.

"The tail is very long and but scantily haired; on the upperside the scales are grey and the hairs dark reddish brown, on the lower the scales are pale yellow and the hairs white; along the centre of the underside, however, there is a distinct narrow line of dark-brown hairs, contrasting with the white ones on either side.

"The ears possess, at about one third the height of the inner margin, a small projecting lobule, which seems to be present in many species of this genus, and to be well worthy of notice, as being very constant in the species in which it is found. The foot-pads are small but distinct, and the surface of the palms and the distal half of the soles are coarsely granulated, as shown in the woodcut.

"The skull is that of a typical *Hesperomys*, but shows only a very faint trace of the supraorbital ridges supposed to be characteristic of the subgenus *Calomys*, to which, however, the species undoubtedly belongs, as proved by its long tail and murine form.

"The following are the dimensions of the two spirit specimens, both of which are adult males:

	a. Inches.	*b*. Inches.
Length of head and body	4.3	4.2
Length of tail	6.4	6.1
Length of head	1.4	
Length of ear	0.55	0.53
Length of hind foot without claws	1.3	1.22
Distance from muzzle to ear-orifice	1.08	

"Measurements of skull of *b*:

	Inch.
Length	1.2
Breadth	0.65
Breadth between orbits	0.16
Length of nasals	0.4
Length of lower jaw from condyle to tip of incisors	0.76

"The species to which *H. coppingeri* appears most nearly allied are *H. lutescens*, Gay, and *H. philippii*, Landb., both from Chili. The first, however, is much larger, being 5.7 inches in length, while its tail is only as long as the trunk. Moreover the skull, as figured by Gay, possesses strong supraorbital ridges, while our three specimens of *H. coppingeri*, as stated above, show but little trace of them. *H. philippii*, though somewhat similar in size and colour, may be readily distinguished by the ex-

treme shortness of its tarsus (0.8 in.); and by the character of its fur, which is described as being short and fine, while that of *H. coppingeri*, as mentioned above, is particularly long and soft." (Thomas, *l. c.*)

Genus ELIGMODONTIA F. Cuvier.

Eligmodontia F. Cuvier, Ann. Sci. Nat. (2), VII, 1837, 168. Type, *Eligmodontia typus*, sp. nov.

Heligmodontia Agassiz, Nomen. Zool., Mamm., Addenda, 5, 1846. Emendation of *Eligmodontia* F. Cuvier.

Eligmodon Thomas, Ann. & Mag. Nat. Hist. (6), XVIII, Oct., 1896, 307. Emendation of *Eligmodontia* F. Cuvier.

Calomys Waterhouse, P. Z. S., 1837, 21 (as a subgenus of *Mus*). Type, *Mus bimaculatus* Waterhouse. Preoccupied by *Callomys* D'Orbigny & Geoffroy.

Callomys Gray, List Mamm. Brit. Mus., 1843, 112 (as a full genus). = *Calomys* Waterhouse.

Hesperomys Waterhouse, Zoöl. Voy. Beagle, pt. ii, Mamm., 1839, 75. No type; proposed to include, apparently, all the New World Muridæ except the Voles and the genus *Neotoma*, or the "Sigmodontinæ." *Mus bimaculatus* was specifically used in defining the characters of *Hesperomys*, and if this species be taken as the type, as it is quite proper to do, *Hesperomys* becomes a synonym of *Calomys* Waterhouse, 1837 (*nec Callomys* D'Orbigny & Geoffroy).

The genus *Eligmodontia* includes at present about 20 commonly recognized species and subspecies. Its range extends from southern Patagonia northward to southwestern Brazil and Bolivia, east of the Andes, and in the Andean region north at least to central Peru. Its metropolis, or area of greatest abundance, includes Argentina, Paraguay, and Bolivia. Four species have been recorded from the region here under consideration, but only one is represented in the Princeton University Patagonian collections.

Eligmodontia and *Phyllotis* appear to be inosculant groups, but lack of material at present writing prevents a satisfactory investigation of the matter. In 1901[1] I felt convinced that the *griseoflava* group was better referable to *Phyllotis* than to *Eligmodontia*, taking *E. typus* and *E. morgani* as the standard for *Eligmodontia*, and *Phyllotis darwini* and *P. xanthopygus* as the standard for *Phyllotis*. As, however, Mr. Thomas,

[1] Bull. Am. Mus. Nat. Hist., XIV, p. 408, Nov. 39, 1901.

with far better means at hand for reaching a correct conclusion, prefers the association of the *griseoflava* group with *Eligmodontia*, this course is reluctantly followed in the present connection, as *griseoflava* was one of the three species originally referred by Waterhouse to his subgenus *Phyllotis*.

ELIGMODONTIA TYPUS F. Cuvier.

Eligmodontia typus F. Cuvier, Ann. des. Sci. Nat., sér. ii, VII, Mars 1837, 168, pl. v, animal, skull, dentition, and intestinal canal. "Environs de Buenos Aires." — Trouessart, Cat. Mamm., ii, 1897, 532. — Lahille, Congr. Cien. Lat. Amer., III, 1899, 186.

Mus elegans Waterhouse, P. Z. S., 1837 (Nov. 21, 1837), 19, Bahia Blanca; Zoöl. Voy. Beagle, Mamm., II, 1839, 41, pl. xii, animal, pl. xxxiv, fig. 2, skull and teeth.

Hesperomys elegans Burmeister, Descrip. phys. Rép. Argent., III, 1879, 220, Rio Chubut, collected by Durnford.

Eligmodontia elegans Thomas, P. Z. S., 1898, 210. Chubut, East Patagonia.

This species is not represented in the present material, but has been recorded from Tomba Point, on the coast, about 60 miles below the mouth of the Rio Chubut. The following description is transcribed from Waterhouse, it being more detailed and satisfactory in form than that given by F. Cuvier, which has a few months' priority of publication.

"Fur very long and soft; general colour of the upper parts of the body pale brownish yellow; the lower portion of the cheeks, and the under parts of the body pure white; the hairs of the ordinary fur of the back are gray at the base, pale ochre near the apex, and brown at the apex; the longer hairs are brownish. On the sides of the body where the longer hairs are less numerous, the pale ochre colour prevails; the hairs on this part as on the back are deep gray at the base, but at a short distance from the apex they are white; nearer the tip shaded into yellow, and at the tip brownish: the limbs externally are of a pale yellow colour. The hairs of the throat and chest are pure white to the root, those on the belly are obscurely tinted with gray at the root. The feet are of a pale flesh-colour, and furnished with white hairs; the fore feet are of moderate size; the thumb nail is small and rounded, and the carpal tubercle is covered with hairs; the tarsi are long, and the white hairs extend over the whole of the under parts; the under side of the toes, however, are but sparingly

furnished. There appears to be but one large tubercle on the under side of the tarsus, and this, which is situated near the base of the toes, is thickly covered with silvery-white hairs. The tail is long, pale brown above, and pale flesh-colour beneath; above, it is furnished with minute brown hairs, and on the under side with white hairs. The ears are rather large, of a pale flesh-colour tolerably well clothed with hairs, which are of a pale yellow colour on the inner side, and white on the outer side—excepting on the fore part, where they are brown. A small tuft of white hairs springs from the base of the ear posteriorly. The hairs of the moustaches are moderate; black at the base, and grayish at the apex.

	Inches.	Lines.	[mm.]
"Length from nose to root of tail	3	7	91
Length of tail	3	9	44.8
Length from nose to ear	1	0	25.4
Length of tarsus	0	10	21
Length of ear	0	6	12.7

"Habitat, Bahia Blanca (September)."—Waterhouse, Zoöl. Voy. Beagle, *l. c.*

Based on a single specimen, collected by Darwin, who says: "Whilst bivouacking one night on shore, amongst some sand hillocks, this mouse, with its tail singed, leapt out of a bush which was placed on the fire. Its hind legs appeared long in proportion to the front, and it did not appear to be very active in endeavouring to make its escape."

Mr. Durnford, in his field notes on this species, published by Mr. Thomas (*l. c.*) says: "Not uncommon among bushes, into which it climbs readily. Comes out in the evening to feed. Like the long-tailed Rat [*Eligmodontia griseoflava*] this species is most numerous in the summer, though during the winter a few may be found. It does not enter the house like its large relative, but is extremely numerous in the thick scrub and brushwood in the neighborhood of the Colony, and universally distributed. It makes a small oval nest of fine grass and any soft material, which it places in the centre of a thick bush. It never burrows in the ground, but is extremely numerous among the thorn-bushes."

F. Cuvier's name *typus* for this species appears to have unquestionable priority over *elegans* of Waterhouse, the signature date of Cuvier's paper on *Eligmodontia* being March, 1837, while the signature of the Proceedings of the Zoölogical Society containing Mr. Waterhouse's paper was not

delivered to the Society by the printer till Nov. 21, 1837. (*Cf.* Sclater, P. Z. S., 1893, 437.)

ELIGMODONTIA MORGANI Allen.

(Plates IX, Fig. 1, Skull; X, Figs. 2 and 3, Teeth.)

Eligmodontia morgani Allen, Bull. Am. Mus. Nat. Hist., XIV, 409, Nov. 30, 1901. Basaltic Cañons, 50 miles southeast of Lake Buenos Aires, Patagonia ("Arroyo Else" on the labels and in the original description).

Pelage very full, long and soft. Above dull ochraceous gray, finely lined with black, sides paler and more buffy, passing into a well-defined pale yellowish lateral line, extending from the sides of the nose to the base of the tail; lower parts pure white, the fur plumbeous at base, the apical half white; ears medium, dusky brown externally, pale buffy gray internally; tail nearly as long as head and body, sharply bicolor, dark brown above, grayish white below, well haired and slightly penicillate; fore and hind feet above grayish white, well covered with short hairs; soles and palms flesh color, sparsely haired, the flesh-colored skin barely showing through the hairs.

Measurements.—Total length (of type), 165 mm.; head and body, 85; tail, 80; hind foot, 23; ear (from dry skin), 13.

Different specimens, apparently adult or nearly so, vary greatly in measurements, as shown by the following: Nine topotypes, all males but one, collected and measured by Mr. Colburn: Total length, 153 (145–165); tail vertebræ, 72.5 (65–80); hind foot, 22.5 (22–23). Five (2 males and 3 females) from the upper Rio Chico, collected and measured by Mr. Peterson: Total length, 165 (148–180); tail vertebræ, 77 (70–84); hind foot, 23 (21–24). Seven specimens from Cape Fairweather and vicinity (all males but one), collected and measured by Mr. Peterson: Total length, 150 (144–170); tail vertebræ, 69.4 (66–77); hind foot, 22.5 (22–24).

Skull much as in *E. typus*, but rather smaller, and with the same character of dentition. Total length (type), 24; basilar length, 17.5; zygomatic breadth, 12; mastoid breadth, 11; interorbital breadth, 4; length of nasals, 10; palate, 5; palatal foramina, 5 × 2; interparietal, 11 × 2.5; upper toothrow, 4; lower jaw, 12; height at condyle, 5.3; lower toothrow, 4.

This species is represented by 48 specimens, of which 17 are from the coast and 31 from the interior, and among the latter are several quite

young, taken in March. The coast specimens were all collected by Mr. Peterson, as follows: Gallegos River, 2 specimens, May 23; Halliday Ranch, 1 specimen, June 24; Coy Inlet, 5 specimens, August 29–31, and November 3–9; Cape Fairweather, 8 specimens, July 11–13. Of the interior specimens, 11 were collected on the upper Rio Chico, by Mr. Peterson, January 31 to February 8 and March 1; 13 are from Basalt Cañons, the type locality, collected by Mr. Colburn, April 4–29; and 8 (mostly quite young) from Swan Lake, collected by Mr. Colburn, March 12–21.

Only about one third of the specimens, or perhaps less, can be considered as fully adult; the others range from one fourth to one half grown, and the remainder from one half grown to nearly full-sized young adults. The younger specimens are darker, grayer, and less fulvous than the adults. The old adults are quite strongly fulvous on the sides as compared with the middle-aged and young adults, as shown by both the upper Rio Chico specimens and the coast series. No. 84216, an old male, "Upper Rio Chico, near Cordilleras, Feb. 3, 1897," is the palest and most fulvous example of all, but seems to be merely an unusually light colored and very fulvous extreme of the series and not specifically different.

This species has externally the appearance of a small-eared *Phyllotis*. Its nearest known ally appears to be *E. typus* (*elegans* Waterhouse), from which it differs in having much smaller ears and shorter tail, the foot and body being nearly as in *E. typus*.

The type of *E. elegans* was collected by Darwin at Bahia Blanca and is much changed in color by exposure for a long time as a mounted specimen. Two other specimens in fair condition from Chubut, eastern Patagonia, identified as *E. elegans* by Mr. Thomas, very closely resemble in color the series of *E. morgani*, but differ from them strikingly in their much larger ears and much longer tails. There are no flesh measurements, but the vertebræ still remain in the tail and the skins are fairly well made up.

ELIGMODONTIA GRACILIPES (Waterhouse).

Mus gracilipes Waterhouse, P. Z. S., 1837 (November 21, 1837), 19 (Bahia Blanca); Zoöl. Voy. Beagle, Mamm., II, 1839, 45, pl. xi, animal, pl. xxiv, fig. 4, skull, teeth and under side of tarsus.

Eligmodontia gracilipes Trouessart, Cat. Mam., ii, 1897, 532. — Thomas, P. Z. S., 1898, 211, Chubut, East Patagonia.

This species was described by Waterhouse from a single specimen obtained by Darwin at Bahia Blanca. It has since been recorded by Thomas from Chubut, East Patagonia, and therefore must be included in the present work. Mr. Waterhouse's description, in his account of the Mammalia of the voyage of the *Beagle*, is as follows:

"General color pale yellowish brown, a tint produced by the admixture of black and pale fawn colour; the hairs of the ordinary fur being of the latter tint near the apex, and dusky at the apex, whilst the longer hairs are black. The feet, tail and under parts of the body and sides of the muzzle, are pure white. All the hairs of the body (which are soft, and of moderate length), are deep gray at the base. The ears are of moderate size, well clothed with hairs, of which those on the inner side are yellowish, and those on the outer are brown on the anterior part, and white on the posterior. A small tuft of white hairs springs from the neck immediately behind the ears; this tuft is hidden when the ears are folded back. The tail is slender and short (being not quite equal to the body in length) of a pale flesh-colour, and sparingly furnished with minute white hairs. The feet are very small and slender, and the naked parts are of a flesh-colour. The sole of the foot is covered with hairs; the toes beneath and the tubercles (which are as in *Mus Musculus*), however, are naked. The hairs of the moustaches are of moderate length, and of a blackish colour, some of them, however, are grayish white.

	Inches.	Lines.	[mm.]
"Length from nose to root of tail	2	10	[53]
Length of tail	1	7	[40]
Length from nose to eye	0	$4\frac{1}{3}$	[9.1]
Length from nose to ear	0	$8\frac{1}{4}$	[15]
Length of tarsus (claws included)	0	$6\frac{1}{2}$	[14]
Length of ear	0	$4\frac{1}{4}$	[9]

"Habitat, Bahia Blanca (September)."

Mr. Durnford (*cf.* Thomas, *l. c.*) refers to this species as less common at Chubut than the other species of *Eligmodontia* found there, and that it "makes its nest in a thick bush about a foot above the ground and of grass torn into fragments."

Eligmodontia griseoflava (Waterhouse).

Mus (*Phyllotis*) *griseoflavus* Waterhouse, P. Z. S., 1837 (Nov. 21, 1837), 28, Rio Negro.

Mus griseoflavus Waterhouse, Zoöl. Voy. Beagle, Mamm., II, 1839, 62, pl. xxii, animal, pl. xxxiv, fig. 16, skull and teeth.

Hesperomys griseoflavus Burmeister, Descrip. phys. Rép. Argent., III, 1879, 219. Rio Chubut, collected by Durnford.

Eligmodontia griseoflava Thomas, P. Z. S., 1898, 210. Chubut, East Patagonia.

Phyllotis griseoflavus Trouessart, Cat. Mamm., 1897, 534.—Lahille, Congr. Cien. Lat. Amer., III, 1899, 187.—Allen, Bull. Am. Mus. Nat. Hist., XIV, 1901, 408.

This species is recorded from Chubut by Mr. Thomas (*l. c.*), and thus comes within the region included in the present work. The following is a transcript of Waterhouse's description in the Mammalia of the Voyage of the *Beagle*.

"Ears large; tail rather shorter than the head and body taken together; tarsi slender, and moderately long; fur long and very soft; general tint of the upper parts of head and body grayish, washed with brownish yellow; on the sides of the body a palish yellow tint prevails; feet, chin, throat, and under parts of body pure white; tail rather sparingly clothed with hairs, those on the apical portion rather long, and forming a slight pencil at the tip; on the upper side and at the tip of the tail the hairs are brown, on the under side they are dirty white; the ears are very sparingly clothed with minute brownish yellow hairs internally; externally, on the fore part, the hairs are rather longer and of a brown colour; the upper incisors are orange, and the lower incisors are yellow; the hairs of the moustaches are long, and of a black colour; the hairs of the back are deep gray at the base, brownish at the tip, and annulated with pale brownish yellow near the tip; the longer hairs are brown; the hairs of the belly are white externally, and gray at the base; on the throat the hairs are white to the root.

	Inches.	Lines.	mm.
"Length from nose to root of tail	6	8	168
Length of tail	5	6	140
Length from nose to ear	1	$4\frac{1}{2}$	35.3
Length of tarsus (claws included)	1	$2\frac{1}{2}$	30.8
Length of ear	0	8	16.8

"Habitat, Northern Patagonia (August)."

Darwin adds: "Inhabits the dry gravelly plain, bordering the Rio Negro."

Respecting the reference of this species to the genus *Eligmodontia* instead of to *Phyllotis*, Mr. Thomas observes:

"I have long realized that the animal commonly known as '*Phyllotis*' *griseoflavus* has so different a skull from that of the typical species of *Phyllotis*, that it could not be considered as really congeneric with them. But, on the other hand, its cranial characters are by no means so different from those of the long-tailed species of *Eligmodontia;* and rather than make a new generic term for it I refer it to that genus, in which it bears to the other species about the same relative proportion in size as *Mus rattus* does to *M. musculus*."

The enamel pattern of the teeth, however, is quite different from that of the typical species of *Eligmodontia*, and the teeth themselves are more hypsodont, as in *Phyllotis*. Externally and in the large size there is also a close agreement with *Phyllotis*.

Mr. Durnford gives the following account (*cf.* Thomas, *l. c.*) of the habits of this species as observed by him near the mouth of the Rio Chubut:

"This Rat is only found close to the Colony [Chubut] in the summer, but at that season it overruns many of the houses and is extremely destructive, eating boots, calico, etc., and is especially fond of gnawing the metal spouts of teapots. What becomes of it in the winter I do not know, but I believe it lies dormant under the scrub and brushwood. It never burrows in the ground, but lives under old logs, bushes, etc., and the female makes a nest, generally in the centre of a thick bush of bark stripped into fine shreds and any soft material it can find. It can jump and climb with great agility."

The *Eligmodontia* (*seu Phyllotis*) *griseoflava* group ranges northward from southern Patagonia over the chaco and pampa regions of Argentina, Paraguay, and Bolivia, and includes *E. griseoflava domorum* Thomas from Tapacari, *E. g. centralis* Thomas from central Cordova, *Phyllotis chacoënsis* Allen from the chaco boreal of Paraguay, and *P. cachinus* Allen from the upper Cachi River, Argentina. These are all closely related and may be merely local forms or subspecies of *griseoflava*, as considered by Mr. Thomas.[1]

Genus PHYLLOTIS Waterhouse.

Phyllotis Waterhouse, P. Z. S., 1837 (Nov. 21, 1837), 28 (as a subgenus of *Mus*). No type designated.

Phyllotis Fitzinger, Sitzungsb. Math.-Nat. Cl. K. Akad. Wiss. Wien, LVI, 1867, 83 (as a full genus).

[1] Ann. & Mag. Nat. Hist. (7), IX, April, 1902, p. 241.

Phyllotis Thomas, P. Z. S., 1884, 449 (as a subgenus of *Hesperomys*).
Mus (*Phyllotis*) *darwinii* Waterhouse designated as type.

Phyllotis, on the one hand, closely approaches *Eligmodontia* (see *antea*, p. 50), and on the other is not very sharply separable from *Reithrodon*, through such species as "*Phyllotis*" *boliviana* and "*Reithrodon*" *pictus*. About 20 to 25 species and subspecies have thus far been assigned to the group, which has about the same geographical range as *Eligmodontia*, namely, from southern Patagonia northward over the plateau region east of the Andes to northern Bolivia, and through the Andean region north to Ecuador. The two Patagonian species here included were both described by Waterhouse in 1837 from specimens collected by Darwin, and are both well represented in the Princeton University Expedition collections.

PHYLLOTIS XANTHOPYGUS (Waterhouse).

(Plates XIII, Fig. 1, Skull; XIV, Figs. 2 and 3, Teeth.)

Mus (*Phyllotis*) *xanthopygus* Waterhouse, P. Z. S., 1837 (Nov. 21, 1837), 28. Santa Cruz, Patagonia.

Mus xanthopygus Waterhouse, Zoöl. Voyage Beagle, Mamm., 1839, 63, pl. xxii, animal, pl. xxxiv, fig. 16, teeth.

Hesperomys (*Calomys*) *xanthopygus* Burmeister, Descript. phys. Rép. Argent., III, 1879, 225 (ex Waterhouse.)

Hesperomys (*Phyllotis*) *xanthopygus* Milne-Edwards, Mission Scient. du Cap Horn, VI, Zool., Mamm., 1890, 20, pl. vi, fig. 2, animal. Santa Cruz, Patagonia.

Phyllotis xanthopygus Trouessart, Cat. Mamm., ii, 1897, 534 (ex Waterhouse and Thomas).—Lahille, Congr. Cien. Lat. Amer., III, 1899, 187.

Adult (November).—Pelage very soft and very long and full. General color above, from the eyes posteriorly, dull brown varied with black-tipped hairs and faintly suffused with buff or pale fulvous, darkest over the median area, the sides more buffy and less dark, passing into a strong buff lateral line, indistinct above; ventral surface whitish (under fur dark plumbeous, scarcely showing at the surface), faintly washed in most specimens with very pale buff, giving the general effect of soiled yellowish white; whole front of head from a point midway between ears and eyes gray, varied with black-tipped hairs; hairs at base of tail rusty fulvous; ears large, dark brown, rather thinly furred; upper surface of feet whitish, palms and soles flesh-color; tail about one half the total length, generally

well haired, especially on the apical half, and penicillate, bicolor, brown above and whitish below.

Adult (February to April).—The pelage is thinner, grayer and darker, with less fulvous suffusion throughout, and the fulvous lateral line very indistinct, evidently from fading.

Young Adults (March and April).—Above dark gray, strongly varied with blackish, and very faintly suffused with fulvous; lower border of sides tinged more or less strongly with fulvous, sometimes forming a poorly defined lateral band; ventral surface gray, sometimes without fulvous wash, or varying from a faint buffy pectoral spot to a large strongly buff area occupying most of the ventral surface.

Measurements.—Six old males (from Basaltic Cañons) measure: Total length, 235 mm. (230–250); tail vertebræ, 115 (110–125); hind foot, 30 (29–30). Four old females measure: Total length, 236 (225–242); tail vertebræ, 115 (110–119); hind foot, 30.6 (28–31). Young adults range in total length from about 205 to 225, with a tail length of 100 to 110. Five adults from the coast (mouth of Rio Coy, all males except one) measure: Total length, 240 (230–247); tail vertebræ, 114.5 (105–116); hind foot, 30.6 (28–32).

An average fully adult skull measures: Total length, 32; basal length, 27; zygomatic breadth, 16.5; width of braincase, 14; interorbital breadth, 4; palatal length, 14; palatal foramina, 7.5; diastema, 8; upper molar series, 5.

Represented by 24 specimens, of which about 17 are fully adult, the rest being more or less immature. Five (3 adults and 2 young) were taken on the upper Rio Chico in February; 5, all adults, at the mouth of the Rio Coy, Nov. 6–10; 6 (mostly immature) at Swan Lake in March, and 9 at the Basaltic Cañons in April. As noted above, they represent three distinct phases of pelage, two of which are seasonal and the other the adolescent stage. The Rio Coy series represents full winter pelage, and the upper Rio Chico series the summer pelage; the Swan Lake and Basaltic Cañons specimens are in the early fall pelage (March and April), and differ strikingly from Rio Coy specimens, taken in November.

Mr. Waterhouse states (Voy. Beagle, *l. c.*) that there were three specimens of this species collected by Mr. Darwin; the specimen in the British Museum, designated as the type, is a rather young individual, and is in

the phase of pelage corresponding to the present March and April specimens taken on the plains at the eastern base of the Andes.

Mr. Darwin says of this species (Voy. Beagle, *l. c.*) : "Extremely abundant in the coarse grass and thickets in the ravines at Point Desire and Santa Cruz ; was caught in a trap baited with cheese."

Mr. Peterson says that the Rio Coy specimens were collected "around a large spring, in heavy grass and brush"; and that the upper Rio Chico specimens were taken "in the Rio Chico valley, close to the river."

Phyllotis xanthopygus, in the full brown pelage of winter, bears a strong resemblance in coloration to *P. micropus*, but it is considerably larger in external measurements, with a relatively longer and a much more hairy tail. The skulls of the two species, however, are practically of the same size. It can be quite closely matched in pelage and color by specimens of *P. darwini*, but the latter has a longer tail and much weaker dentition. Mr. Waterhouse compared it with his *Phyllotis griseoflavus*, probably its nearest ally, from northern Patagonia (Rio Negro), from which he says it differs in much smaller size, relatively much shorter tail, and in the structure of the molar teeth, as illustrated in plate xxxiv of the "Voyage of the Beagle" (Mammalia).

PHYLLOTIS MICROPUS (Waterhouse).

(Plates XII, Fig. 13, Skull ; XIV, Fig. 1, Teeth.)

Mus micropus Waterhouse, P. Z. S., 1837, 17 (Santa Cruz River, Patagonia) ; Zoöl. Voyage Beagle, Mamm., II, 1839, 61, pl. xx, animal, pl. xxxiv, fig. 13, teeth. Interior plains of Patagonia, in lat. 50°, near the banks of the Santa Cruz.

Hesperomys (*Habrothrix*) *micropus* Burmeister, Descrip. phys. Rép. Argent., III, 1879, 217 (ex Waterhouse).

[*Akodon*] *micropus* Trouessart, Cat. Mamm., ii, 1897, 536 (ex Waterhouse and Burmeister). — Lahille, Congr. Cien. Lat. Amer., III, 1899, 188.

Adult (February). — Above yellowish brown, with a slightly rufescent cast, strongly varied with black-tipped hairs ; sides lighter, more yellowish ; nose less yellow, dusky gray ; below gray, washed more or less with buff or tawny, chiefly on the pectoral and post-pectoral areas ; ears large, well haired, similar in color to the median dorsal area ; tail rather more than one third of the total length, bicolor, dark brown above, gray or yellowish

gray below thinly clothed with short hairs in young specimens, nearly naked in adults; upper surface of the feet yellowish white or nearly flesh-color; palms and soles naked, the former yellowish flesh-color, the latter darker, more brownish.

Young specimens differ little in color from the adults, but the pelage is of a softer, more woolly texture.

Measurements. — Eight adult males measure: Total length, 221 mm. (212-237); tail vertebræ, 92 (85-100); hind foot, 29 (27–30). Ten adult females measure: Total length, 221 (215–235); tail vertebræ, 93 (85–100); hind foot, 29 (28–30). A young adult and an adult skull measure respectively: Total length, 29.5, 32; basal length, 25, 28; zygomatic breadth, 17, 19; mastoid breadth, 8, 9.5; interorbital breadth, 3.8; length of nasals, 7.3, 8; palatal length, 13, 15; palatal foramina, 7, 7.4; diastema, 7, 8; upper molar series, 5.2, 5.3.

Of the fifty specimens of this species about one half are fully adult, the rest being more or less immature, but mainly "young adults." Four were collected by Mr. Colburn — two at Swan Lake in March, and two at Basaltic Cañons in April — and the rest by Mr. Peterson, nearly all during the first half of February (January 31–February 17), and mostly in the Rio Chico valley, close to the river. Two others were taken on the Pacific slope in March.

The coloration of the upper parts is very uniform throughout the series, varying slightly in general tone on the back from yellowish brown to a slight rufescent tinge, the latter seeming to characterize very old specimens. The whitish gray ventral surface varies from a slight tinge of deep buff over a limited portion of the middle region to a much deeper rusty buff, covering a much larger area. Some specimens quite lack the buffy wash.

A portion of the specimens forming the present series was identified by comparison with Waterhouse's type, still extant in the British Museum — a fairly well preserved skin with an imperfect skull. This specimen, according to Darwin's note, was "caught in the interior plains of Patagonia, in latitude 50°, near the banks of the Santa Cruz."

Mr. Peterson states (MSS. notes) that this is the most common species met with on the "Rio Chico Cordillero, especially in the heavy grass near water; but was also caught in timber at some distance from water." It appears to have been rare further north in the more open country where

Mr. Colburn worked, he securing only four specimens during six weeks of constant trapping.

Genus REITHRODON Waterhouse.

Reithrodon Waterhouse, P. Z. S., 1837 (Nov. 21, 1837), 29; Zoöl. Voy. Beagle, Mamm., 1839, 68. No type specified.

Reithrodon Coues, Proc. Acad. Nat. Sci. Phila., 1874, 185. Type, *R. cuniculoides* Waterh. — Thomas, Ann.& Mag. Nat. Hist. (7), VIII, Sept. 1901, 254. — Allen, Bull. Am. Mus. Nat. Hist., XIX, May, 1903, 194 (sub *Euneomys*).

Variants or emendations are: *Rithrodon* Agassiz, 1846; *Rheitrodon* Roger, 1887; *Rhithrodon* Flower & Lydekker, 1891.

The genus *Reithrodon*, as originally constituted in 1837, consisted of two species, *R. typicus* and *R. cuniculoides*. Later, other species of American Muridæ with grooved upper incisors were referred to it, including the North American genus now known as *Reithrodontomys*, although these two groups have little in common beyond the superficial character of grooved upper incisors. Other species formerly associated with it are the genera *Euneomys* Coues and *Sigmomys* Thomas, neither of which prove to have more than a superficial likeness to *Reithrodon* as now restricted and as originally constituted.

Two years later, in 1839, Waterhouse himself added to it a third species, *R. chinchilloides*, which, proving not to be congeneric with the others, has since become the type of the genus *Euneomys*.

In 1874, Coues (*l. c.*) divided *Reithrodon* into "*Reithrodon* proper," with *R. cuniculoides* as the type, and *Euneomys*, a new subgenus of *Reithrodon*, with *R. chinchilloides* as the type. In 1901, Thomas (*l. c.*) adopted these two divisions as full genera, and, having previously removed his *Reithrodon alstoni* as the type of a new genus *Sigmomys*,[1] arranged the "South America groove-toothed Muridæ" in three genera, *Reithrodon*, *Euneomys* and *Sigmomys*, which really have little in common. Later a somewhat detailed comparison of *Reithrodon* and *Euneomys* was given by the present writer.[2]

The genus *Reithrodon* is represented by four species and an additional subspecies, and, so far as known to me, is restricted to Patagonia, Argen-

[1] Ann. & Mag. Nat. Hist. (7), VIII, Aug., 1901, p. 150.

[2] Bull. Am. Mus. Nat. Hist., XIX, 1903, pp. 194, 195.

tina and Paraguay. Besides those here included, *R. typicus* Waterh. was described from specimens taken at Maldonaldo, and it has been reported as occurring in southern Paraguay and contiguous portions of Argentina. The other forms are thus far known only from southern Patagonia and Tierra del Fuego.

Reithrodon cuniculoides Waterhouse.

Reithrodon cuniculoides Waterhouse, P. Z. S., 1837 (Nov. 21, 1837), 30 (Santa Cruz, Patagonia); Zoölogy Voyage Beagle, Mamm., 1839, 69, pl. xxvi, animal, pl. xxxiv, fig. 2, skull and teeth. — Coues, N. Am. Rodent., 1877, 119 (ex Waterhouse). — Burmeister, Descript. phys. Rép. Argent., III, 1879, 230 (ex Waterhouse). — Milne-Edwards, Miss. Scient. du Cap Horn, VI, Zool., Mamm., 1890, 10, pl. ii, animal (Santa Cruz, Patagonia). — Trouessart, Cat. Mamm., ii, 1897, 533. — Thomas, Ann. and Mag. Nat. Hist. (7), VIII, Sept., 1901, 254.

Adult (April). — Above pale fulvous gray strongly varied with black-tipped hairs, the pelage being dark plumbeous for the basal three fourths or four fifths and ending in a band of pale creamy buff, with a profuse intermixture of longer, coarser black-tipped hairs; sides lighter, more yellowish, passing gradually into the nearly uniform ochraceous buff of the ventral surface; inside of the thighs whitish; ears large, well clothed with short hairs, dusky brown externally, deep buff internally, with a tuft of buffy hairs at the anterior base and a postauricular patch of ochraceous buff; upper surface of the feet white or faintly creamy white; palms naked, light flesh-color; soles heavily furred as far as the base of the toes, the furred portion dusky brown, as are the tubercules, but the under surface of the toes flesh-color; tail rather more than one third the total length, thickly haired, yellowish dusky brown above, sides and below whitish.

Measurements. — Eight adults measure: Total length, 225 mm. (215–230, with one 240); tail vertebræ, 86 (80–90, with one 100); hind foot, 34 (33–35). Ten females measure: Total length, 220 (210–235); tail vertebræ, 88 (80–95, with two at 100); hind foot, 33 (32–34).

Adult skulls measure in total length from 33–35 mm., and in zygomatic breadth from 18–19.

Represented by 28 specimens, of which 21 were collected at the Basaltic Cañons in April, and 4 at Swan Lake in March and May, by Mr. Colburn; the other three are from the coast region, two of which were collected near

Santa Cruz, in February, by Mr. Colburn, and the other at the mouth of the Rio Coy, by Mr. Peterson, November 10. This specimen has the ears nearly naked and dark brown on both surfaces, and the general coloration is browner and less olivaceous than in the March, April and May specimens.

Mr. Peterson's manuscript notes indicate that some of the specimens taken were "caught in heavy grass, close to springs of water."

The original specimens described by Waterhouse were taken by Darwin, who says: "Specimens were procured at Port Desire, St. Julian, and Santa Cruz; at this latter place they were caught in numbers (in traps baited with cheese), both near the coast and on the interior plains. A specimen from Santa Cruz weighed 1336 grains. In the early part of January, there were young individuals at Port St. Julian." (Zoöl. Voy. Beagle, Mamm., p. 71.)

Mr. Colburn's localities show that the species ranges in the interior to one hundred and fifty or two hundred miles northwest of St. Julian and Santa Cruz.

Reithrodon cuniculoides obscurus Allen.

Reithrodon cuniculoides obscurus Allen, Bull. Am. Mus. Nat. Hist., XIX, 190, May 9, 1903. Punta Arenas, Patagonia.

Similar to *Reithrodon cuniculoides* but darker throughout, the upper parts dark brown, varied with black-tipped hairs and suffused with fulvous, the sides yellowish, and the ventral surface brownish ochraceous; inner side of thighs and anal region whitish; top of head blackish, slightly varied with buff-tipped hairs; sides of nose and cheeks brownish ochraceous like the ventral surface; ears very thinly haired, brown externally, brownish buff internally, with a deep ochraceous buff postauricular patch; upper surface of feet clear white; tail blackish above along median line, sides and below grayish white.

Measurements (of type, from dry skin). — Total length, 195 mm.; head and body, 130; tail, 65; hind foot, 34. (The tail appears to have lost a small portion of the tip.) Skull (imperfect), length of nasals, 15.5; palatal length 18; palatal foramina, 10; diastema, 9.5; upper molar series, 6.

Unfortunately represented by only the type specimen, which has no flesh measurements. The skull shows the specimen to be fully adult, and larger than any skull in the large series of *R. cuniculoides*. It is characterized by its very strong, dark coloration, between which and the darkest, most-

deeply colored specimen in a series of 28 examples from the coast region, near Santa Cruz, there is a striking contrast through the greater depth and intensity of all the tints. Considering the climatic conditions of the two regions — the moist, forested country of the Punta Arenas district and the open, arid plains of the Santa Cruz district — the differences here shown in the coloration of the two phases conform to what would be expected to result from such diverse physical conditions. The differences are certainly not to be accounted for by season or age. It finds an exact parallel in the cases of *Akodon xanthorhinus* as compared with *A. canescens* and *A. michælseni* as compared with *A. macronyx*.

Reithrodon hatcheri Allen.

(Plate XIV, Figs. 8–8*d*, Skull.)

Reithrodon hatcheri Allen, Bull. Am. Mus. Nat. Hist., XIX, 191, May 9, 1903. Pacific slope of the Cordilleras, upper Rio Chico de Santa Cruz, Patagonia.

Similar in size and proportions to *R. cuniculoides*, but much darker, and with much less fulvous suffusion.

Adult male (type), March. — Above dark grayish brown, varied with black-tipped hairs, faintly suffused with grayish fulvous; sides paler, passing gradually into the pale buff of the ventral surface; sides of nose, lower border of cheeks, lower border of flanks, and whole ventral surface cream-buff, except inside of thighs and adjoining portion of ventral surface; ears rather thinly haired, externally dull brown, internally yellowish buff, the hairs at the anterior base of the ears whitish and the postauricular patch pale buff; upper surface of the feet white; soles of hind feet to base of toes densely haired, dark brown, toes flesh-color; tail with a narrow brown stripe above, sides and below dull whitish.

Measurements. — Type: Total length, 230 mm.; tail vertebræ, 78; hind foot, 34; Seven specimens (4 males and 3 females) measure; Total length, 215 (200–230); tail vertebræ, 77 (75–82); hind foot, 33.3 (32–35).

Skull (type). — Total length, 35.7; basal length, 31; zygomatic breadth, 20.5; interorbital breadth, 4; length of nasals, 16; palatal length, 17.5; palatal foramina, 9; diastema, 8.5; upper molar series, 6.4.

Represented by ten specimens, all collected by Mr. Peterson in the Cordilleras at the head of the Rio Chico de Santa Cruz, and all but one

(the type, taken March 11) between February 4 and 21, 1897. Part of the specimens, including the type, are in the dress of the breeding season, while others have partly or wholly acquired the postbreeding dress. These have a stronger suffusion of yellowish buff on the sides and ventral surface, but are otherwise similar to the type. A quarter-grown young example is similar in general coloration to the adults except that the ears have the external surface blackish and the internal surface deep buff, with the hairs at the anterior base of the ears and the postauricular patch also deep buff, in prominent contrast with the surrounding pelage, as is not the case in the adults.

Reithrodon hatcheri is readily distinguishable from *R. cuniculoides* by its much darker and less fulvous coloration, the contrast in color between the two series being conspicuously noticeable. There are apparently no cranial differences of importance.

Genus EUNEOMYS Coues.

Euneomys Coues, Proc. Acad. Nat. Sci. Phila., 1874, 185 (as a subgenus of *Reithrodon*). Type, *Reithrodon chinchilloides* Waterh. — Thomas, Ann. & Mag. Nat. Hist. (7), VIII, Sept., 1901, 254 (as a full genus). — Allen, Bull. Amer. Mus. Nat. Hist., XIX, May, 1903, 194.

The early history of *Euneomys* has already been given under that of *Reithrodon*. The two genera differ so radically in certain cranial characters, especially in the structure of the last two molars, both above and below, that they have no close relationship, and the two are placed together for treatment in the present connection only as a matter of convenience. Their differences were, in part, clearly indicated by the late Dr. Coues, on the basis of Waterhouse's plates of the skulls and teeth of the two species Coues designated respectively as the types of the two groups. These I have already summarized in another connection as follows:

"The most important of these [the differential characters pointed out by Coues] are: (1) 'Anterior root of zygoma deeply emarginate in front' in *Reithrodon* and 'about straight in front' in *Euneomys;* (2) 'palate ending much behind the molar series and showing a median ridge intervening between lateral paired deep excavations' in *Reithrodon*, and 'palate ending nearly opposite the last molars, slightly ridged or excavated' in *Euneomys;* (3) 'pterygoid fossæ deeply excavated, and the bones very closely approximated' in *Reithrodon*, and 'pterygoid fossæ shallow and these bones less

approximated' in *Euneomys;* (4) 'condyloid process of lower jaw concave internally' in *Reithrodon*, and 'condyloid process of the lower jaw flat internally' in *Euneomys;* (5) 'coronoid process slender, very oblique' in *Reithrodon*, and 'coronoid process very broad, nearly vertical' in *Euneomys*. To these may be added (6) the very different enamel pattern of the molar teeth in the two groups, in *Reithrodon* the folds being transverse with the outer and inner loops alternating, and in *Euneomys* oblique, with one less fold in each of the last two upper teeth, and in the first two lower teeth—a very radical difference in tooth structure, which alone warrants the generic separation of the two groups. As Waterhouse figured the crown surface of the teeth in only *R. cuniculoides*, this most important difference of all necessarily escaped Coues's attention.

"In both these genera—*Reithrodon* and *Euneomys*—the tooth structure is remarkably distinctive for genera of Muridæ, and, as compared with each other, presents almost the extremes of unlikeness. But a further noteworthy difference (7) is seen in a pair of depressions on the posterior third of the palatal surface in *Euneomys*, which are absent in *Reithrodon* and in all the allied genera."

The only species I can confidently refer to *Euneomys* are the two described below, namely *E. chinchilloides* (Waterh.), from Tierra del Fuego, and *E. petersoni*, from the upper Rio Chico, in the foothills of the Cordilleras, Patagonia.

Phyllotis boliviensis and *P. pictus*, which have been referred to *Euneomys*, appear to be merely somewhat aberrant forms of *Phyllotis*.

Euneomys chinchilloides (Waterhouse).

Reithrodon chinchilloides Waterhouse, Zoöl. Voyage Beagle, II, Mammalia, 1839, 72, pl. xxvii, animal, pl. xxxiv, fig. 20, skull and teeth. "South shore of the Strait of Magellan, near the eastern entrance."—Burmeister, Descrip. phys. Rép. Argent., III, 1879, 217 (ex Waterhouse).—Milne-Edwards, Mission Scient. du Cap Horn, VI, Zool., Mamm., 1890, 29, pl. iii, animal. Orange Bay, southern Tierra del Fuego.

Reithrodon (*Euneomys*) *chinchilloides* Coues, Proc. Acad. Nat. Sci. Phila., 1874, 185, footnote; Nat. Hist. No. 1, Muridæ, 1874, 17; N. Am. Roden., 1877, 119.

As this species is unrepresented in the present collection, the description here given is transcribed from Waterhouse.

"*Description.*—Ears small; tail shorter than the body; tarsus moderate; fur long and extremely soft. General hue of the upper parts of the head and body ashy brown; lower part of the cheeks and sides of the body are of a delicate yellow colour; the under parts of the head and body and the rump are cream colour. The ears are blackish; the tail is tolerably well clothed with longish hairs, which are, however, not so thickly set as to hide the scales—on the upper side they are blackish brown; on the sides and beneath they are white. The feet are white. All the fur is of a deep gray colour at the base; the hairs of the back are of a very pale yellow colour (almost white) near the tip, and brown at the tip; the longer hairs are black at the apex. The incisors are yellow; the hairs of the moustaches are numerous and very long—some of them are whitish, and others are black at the root, and gray at the apex.

	Inches.	Lines.	[mm.]
"Length from nose to root of tail	5	0	127
" of tail	2	4	59
" from nose to ear	1	2	25.8
" of tarsus (claws included)	1	0	25.4
" of ear	0	5½	12.6

"Habitat, South shore of the Strait of Magellan, near the Eastern entrance."—Waterhouse, *l. c.*

Milne-Edwards (*l. c.*) states that it was obtained at Orange Bay, where, however, only two examples were secured during a long sojourn there by the French Mission. Little therefore appears to be known regarding its distribution or habits.

Euneomys petersoni Allen.

(Plates XIII, Fig. 4, Skull; XIV, Figs. 6 and 7, Teeth.)

Euneomys petersoni Allen, Bull. Am. Mus. Nat. Hist., XIX, 192, May 9, 1903. Near Cordilleras, upper Rio Chico de Santa Cruz, Patagonia.

Similar in coloration to *Phyllotis xanthopygus*, but very much smaller, with a relatively very short tail and naked soles, but the upper incisors as strongly grooved as in *Reithrodon cuniculoides*.

Adult (type), February.—Pelage very long and soft, almost woolly. Above dark gray-brown, varied with blackish and fulvous, the pelage being plumbeous black for the basal four fifths with an apical band of brownish fulvous, and many longer black hairs intermixed; sides much paler and more

fulvous, the fulvous increasing in intensity along the lower border; ventral surface soiled white, the fur being basally very dark plumbeous and broadly tipped with yellowish white; ears dark brown on both surfaces and very thinly haired, the surrounding fur concolorous with that of the anterior dorsal surface; sides of nose and lower border of cheeks whitish gray with a faint tinge of yellowish; soles naked except the posterior third, dark flesh-color; upper surface of fore and hind feet pale flesh-color, nearly white; tail one third or less than one third of the total length, well clothed, dusky brown above, sides and below white.

Measurements.—Total length, 175 mm.; tail vertebræ, 60; hind foot, 26. Three other specimens (young adults) measure: Total length, 160 (150–165); tail vertebræ, 57 (50–60); hind foot, 25 (25–25).

Skull.—Long and narrow, the interorbital and rostral portions especially elongated; postpalatal fossa narrow and V-shaped, but not quite so narrow and pointed in front as in *Reithrodon cuniculoides;* front border of zygomatic plate as in *Phyllotis, Oryzomys,* etc., lacking the pointed superior process seen in *Reithrodon* and *Sigmodon;* bullæ small and pointed, as in *Phyllotis;* upper incisors deeply grooved; molars brachyodont as in *Phyllotis;* but very broad and heavy—not hypsodont as in true *Reithrodon;* lower jaw short and heavy, to support the thickened molars; posterior end of lower incisors encapsuled, forming a prominent process on the outer sides at the base of the condyloid process. Dimensions (type): Total length, 30.5; basal length, 26.5; zygomatic breadth, 17.5; interorbital breadth, 3.5, width of braincase, 14; length of nasals, 14; palatal length, 14.5; palatal foramina, 8; diastema, 8.5; upper molar series, 5.2; width of molar[1], 1.8; lower jaw, length (inner base of incisors to posterior border of condyle), 18; height at condyle, 15; lower molar series, 5.5.

Represented by four specimens, an adult female that had suckled young, and three younger specimens, nearly adult, all taken by Mr. Peterson, in the Cordilleras at the head of Rio Chico de Santa Cruz, Feb. 8–14, 1897. These specimens are all quite similar in coloration, except that the younger ones are grayer than the adults with much less fulvous suffusion, and with very little fulvous on the flanks and ventral surface.

This species finds its nearest ally in *Euneomys chinchilloides* (Waterhouse), known thus far only from Tierra del Fuego, which it apparently closely resembles in size and coloration.

Genus AKODON Meyen.

Akodon Meyen, Nov. Act. Acad. Cæs. Leop.-Carol., XVI, 1833, 599. Type, *Akodon boliviense* Meyen, sp. nov.

Acodon Tschudi, Fauna Peruana, Mamm., 1844, 177. Emendation of *Akodon*.—Thomas, Ann. & Mag. Nat. Hist. (6), XIV, Nov., 1894, 360. "Syn. *Habrothrix*, Waterh. 1837."

Abrothrix Waterhouse, P. Z. S., 1837, 21 (subgenus of *Mus*). Type, *Mus* (*Abrothrix*) *longipilis* Waterh., sp. nov.—Gray, Cat. Mam. Br. Mus., 1843, 114 (full genus).—Thomas, P. Z. S., 1884, 450 (subgenus of *Hesperomys*); P. Z. S., 1896, 1020 (full genus).

Chelemys Thomas, Ann. & Mag. Nat. Hist. (7), XII, Aug., 1903, 242 (subgenus of *Akodon*). Type, *Hesperomys megalonyx* Waterhouse.

The genus *Akodon*, as currently limited, includes nearly one hundred species, covering quite a diversity of forms, which differ in size, texture of pelage, coloration, and proportion of parts, and it will doubtless be found advisable to divide the group, when better known, into a number of subgenera, although in cranial and dental characters there is great uniformity of structure, and no very evident lines of division. In general they are heavy-bodied, short-limbed, short-tailed, vole-like mice, with ears small to medium, pelage generally soft and full but sometimes short and velvety, and claws of ordinary size or strongly developed and fossorial. The color above varies from mouse-gray to dark brown, with or without reddish brown on the back, or nearly uniform dark yellowish brown; the ventral surface varies from white or whitish gray to dark gray, or, as in the *A. caliginosus* group, to nearly as dark as the color of the back. In the *A. pulcherrimus* group there is a distinct pattern of white markings on the sides of the head, nearly enclosing the ears. The species vary in size from the size of a house mouse to that of the larger species of *Microtus*. The teeth vary little in structure, but very much, relatively, in size, some of the fossorial forms, like *A. macronyx*, having much heavier dental armature, relative to the size of the animal, than the *A. xanthorhinus* group.

Sufficient material is not at present available for a critical revision of the group, which evidently may be divided for convenience into several fairly well-marked sections, characterized mainly by external characters. Mr. Thomas has already separated the big-clawed Akodonts as a sub-

genus, *Chelemys*, with *A. megalonyx* (Waterhouse) as the type, to include *A. macronyx* and *A. vestitus* Thomas. Another natural group, of at least subgeneric value, consists of *A. caliginosus* (Tomes), *A. urichi* All. & Chapm., *A. irazu* and *A. venezuelensis* Allen, *A. teguina* (Alston), etc.; *A. pulcherrimus*, with its large ears and striking color-pattern, is possibly also separable from such forms as *A. canescens*, *A. xanthorhinus* and their allies.

For the purpose of convenient comparison, figures are given of the skull and dentition of several of the leading types of *Akodon* on plates XI and XII of this work, namely, *A. xanthorhinus, A. canescens, A. caliginosus, A. pulcherrimus, A. suffusus*, and *A. vestitus.*

The genus *Akodon* has a wide geographical distribution, being represented from Costa Rica southward to the Straits of Magellan, and is especially prolific in specific and subspecific forms throughout the Andean region. It is represented in the collections made in Southern Patagonia by the Princeton University Patagonia Expeditions by five species, four of which—*A. xanthorhinus, A. canescens, A. suffusus* and *A. vestitus*—are each represented by large series of specimens, while the fifth, *A. michælseni*, by a single excellent skin, without, however, the skull.

Besides these Philippi described in 1900 a *Mus pachycephalus*, which appears to be an *Akodon*, with the statement "Habitat in Freto Magellanico"; but the description is not satisfactory, and the species is not here formally included.

Akodon xanthorhinus (Waterhouse).

Mus xanthorhinus Waterhouse, P. Z. S., Nov. 21, 1837, 17; Zoöl. Voyage Beagle, Mamm., 1839, 53, pl. xvii, fig. 1 (animal). "Hardy Peninsula, Tierra del Fuego (February)."

Hesperomys (Habrothrix) xanthorhinus Thomas, P. Z. S., 1881, 5, part; the Sandy Point specimen only.

Adult (January).—Above dull yellowish brown, closely resembling July specimens of *A. canescens;* underparts whitish gray; nose, feet, and tail also similar to these parts in *canescens*—pale rusty fulvous.

Measurements.—Adult male, Punta Arenas, Chili, Jan. 1, 1898: Total length, 151 mm.; tail vertebræ, 62; hind foot, 20. Skull (4 adults), total length, 25 (24.6–25.3); greatest width of brain case, 11.35 (11–11.6).

This species is represented by 10 specimens collected by Mr. Colburn,

about January 1, 1898, at Punta Arenas, of which 7 are adult and 3 immature. Only one of the adults has measurements or is marked for sex. The species is entirely unrepresented in the large series (about 100 specimens) of Akodonts collected by Colburn and Peterson in the Santa Cruz region of Patagonia, and I very much doubt whether it is found there.

These specimens are all in thin summer pelage, and are thus comparable with the gray phase of *A. canescens*, which is the corresponding seasonal pelage of that species. They are thus readily distinguishable in coloration when specimens of corresponding seasons are compared, but summer specimens of *A. xanthorhinus* have a general resemblance in coloration to winter specimens of *A. canescens*. But *A. xanthorhinus* is much the larger animal, although the proportions are similar. The skull, however, is not only larger (averaging about 3 mm. longer), but has the rostral portion of the skull relatively much more attenuated, it being more than one half of the basal length of the skull instead of less than one half, as in *A. canescens*. These specimens agree with Waterhouse's description and type, and there can be no question of their correct identification.

In the original description of *A. xanthorhinus* (*l. c.*) the type locality is given as "Santa Cruz," but in the "Voyage of the Beagle" (*l. c.*) it is given as "Hardy Peninsula, Tierra del Fuego," where also Darwin states: "This species was caught on the mountains, thickly covered with peat, of Hardy Peninsula, which forms the extreme southern point of Tierra del Fuego." This seems to settle the case beyond question that Hardy Peninsula and not Santa Cruz is the type locality of *A. xanthorhinus*. Mr. Waterhouse further says (*l. c.*, p. 55): "The specimens of this animal [*M. xanthorhinus*] are both from Patagonia; one of the specimens of *Mus xanthorhinus* was brought by Mr. Darwin from Tierra del Fuego; and as the other formed part of Captain King's collection, it in all probability came from the same locality."

Waterhouse had, curiously, an old and young specimen each of *Mus xanthorhinus* and *M. canescens;* of the former one specimen is still extant in the British Museum, but the other seems to have been lost, although, as noted below (p. 73), both specimens of *M. canescens* still remain. The specimen of *M. xanthorhinus* is B. M. No. 55–12–24–156, and is labelled "Hardy Peninsula, Ex. Coll. C. Darwin," and should of course stand as the type.

Mr. Waterhouse seems to have been in doubt as to whether *M. xanthorhinus* and *M. canescens* were really distinct species. He says in the "Voyage of the Beagle" (*l. c.*, p. 54): "It was with some hesitation that I described this [*M. canescens*] as a distinct species in the Society's Proceedings. I have now re-examined the specimens, and still am unable to satisfy myself whether they are varieties of *Mus xanthorhinus* or not. Both of *Mus canescens* and of *Mus xanthorhinus*, I have before me what I imagine to be an adult and a young specimen. The adult and the young of *M. xanthorhinus* agree in being of a *yellowish-brown* colour, and in having the muzzle and tarsi deep yellow; both specimens of *Mus canescens* are of a gray colour, with an indistinct yellow wash, the muzzle and tarsi being tinted with yellow, as in *M. xanthorhinus*." These are just the differences, as shown by the present material, that distinguish the two species, as regards coloration. But there is considerable difference in size, *xanthorhinus* being the larger, especially as shown by the skull, as already stated, which also differs markedly in form in the two species.

In examining the types of these species in the British Museum, in July, 1901, I found that they had been misassigned, the two specimens of Waterhouse's *Mus canescens* having been identified, respectively, as the types of *M. canescens* and *M. xanthorhinus*, the Port Desire specimens being designated as the type of *M. canescens*, and the Santa Cruz specimen as the type of *M. xanthorhinus*, while the Hardy Peninsula specimen, the real type of *M. xanthorhinus* was not designated as a type. This probably explains the record made, on the authority of Mr. Thomas, in Milne-Edward's report on the mammals collected by the Mission Scientifique du Cap Horn (Mammals, p. 28), of specimens of *Akodon xanthorhinus* from Santa Cruz, Patagonia, which record is only intelligible on the basis of the above explained misidentification of Waterhouse's type.

Akodon canescens (Waterhouse).

Mus canescens Waterhouse, P. Z. S., Nov. 21, 1837, 17; Zoöl. Voyage Beagle, Mamm., 1839, 54. Port Desire.

Hesperomys (*Calomys*) *canescens* Burmeister, Descrip. phys. Rép. Argentine, III, 1879, 227 (ex Waterhouse).

Hesperomys (*Habrothrix*) *xanthorhinus* Thomas, in Milne-Edwards, Miss. Scient. du Cap Horn, VI, Zoologie, Mamm., 1890, p. 28, pl. vi, fig. 1, animal. Santa Cruz de Patagonie.

Akodon canescens Thomas, P. Z. S., 1898, 211, Chubut, E. Patagonia.

Adult (March and April).—General color above gray, faintly suffused with fulvous and varied slightly with black-tipped hairs; below whitish gray, the basal portion of the fur plumbeous, the tips whitish; sides and front of nose pale rusty fulvous; ears rusty brown; upper surface of fore and hind feet yellowish white or pale rusty fulvous; tail rather indistinctly bicolor, darker above and lighter below, with usually a faint rusty tinge throughout. The ventral surface and sides are often faintly washed with pale fulvous.

Half grown young are almost indistinguishable in coloration from the adults.

Adult (July).—Pelage longer and fuller, and general coloration above yellowish gray-brown, the general tone darker and browner than in April specimens; under parts whiter and with rarely any tinge of buff; sides of nose more rusty, and upper surface of feet more buffy. The difference between the gray summer pelage and the darker and more fulvous brown winter pelage is quite strongly shown in March, April and July specimens from practically the same locality.

The two series from the Rio Coy, consisting of five specimens taken in November and others taken the last of August, well show the two pelages, and indicate that the gray pelage is worn from about November till May, and the brown pelage from about June to September as is further shown by specimens from the vicinity of Cape Fairweather.

Measurements.—Many of the specimens are more or less immature. Throwing out these, save possibly a few young adults, the series, collected and measured by Mr. Colburn, gives the following: 16 males, total length, 132 mm. (125–140, with one reaching 150); tail vertebræ, 50.9 (50–55); hind foot, 19.7 (19–20): 16 females, total length, 135.3 (125–145); tail vertebræ, 50 (45–55); hind foot, 20 (19–20). Fully adult specimens appear to rarely fall below 130 mm. in total length, and very few exceed 140 mm.

Seven males and four females collected and measured by Mr. Peterson, from the upper Rio Chico de Santa Cruz, give similar results, as follows: 7 males, total length, 136 (125–151); tail vertebræ, 50 (46–54), hind foot, 20 (18–21): 4 females, total length, 137 (126–148); tail vertebræ, 50.7 (45–55); hind foot, 20 (20–20).

Thirteen specimens from Cape Fairweather, all males, collected and

measured by Mr. Peterson, give the following: Total length, 125.4 (120–135); tail vertebræ, 45.6 (42–51); hind foot, 20.4 (20–21). Eight specimens from Coy Inlet, collected and measured by Mr. Peterson, all males but one: Total length, 138.5 (130–144); tail vertebræ, 52 (43–60); hind foot, 20 (19–20).

The principal measurements of 4 adult skulls are: Total length, 22.9 (22.3–24); greatest width of brain case, 10.8 (10.7–11).

Represented by 95 specimens, collected partly in the coast region and partly on the upper Rio Chico and the plains southeast of Lake Buenos Aires. The coast specimens comprise 4 taken near Mount Observation, February 21, by Mr. Colburn, and 35 from points further southward, taken by Mr. Peterson, as follows: Rio Gallegos, 2 specimens, May 23; Halliday Ranch, mouth of the Rio Gallegos, 3 specimens, June 24; Cape Fairweather, 13 specimens (all males), July 5–13; Rudd Ranch, near Cape Fairweather, 8 specimens, July 27 and 28; Coy Inlet, 9 specimens, August 8 and 31, September 1, and November 7–11. The specimens from the interior include 14 specimens collected on the upper Rio Chico, by Mr. Peterson, January 31 (7 specimens), February 3–6 (5 specimens), and March 26 (2 specimens); and 34 collected by Mr. Colburn at Basalt Cañons, April 8–28, and 5 at Swan Lake (March 18–20 and May 4 and 15).

The summer and fall specimens from the interior are darker and grayer and much less fulvous than the winter specimens from the coast, but there are enough specimens collected at intermediate dates to show that the difference is, almost beyond question, seasonal and not geographical.

The species thus seems to range across southern Patagonia from Cape Fairweather to the Cordilleras. It was not, however, obtained by Mr. Colburn at Punta Arenas, where he collected only *A. xanthorhinus*.

The two specimens on which the species was originally based by Waterhouse were collected by Darwin, one at Port Desire and the other at Santa Cruz. Only Port Desire is mentioned in the original description, but in the Voyage of the "Beagle" (Mamm., *l. c.*) the "habitat" is given as "Santa Cruz and Port Desire (December)." Both these specimens are still preserved in the British Museum and have been compared with a large number of specimens from the present series. These types are Nos. "55–12–24–157. Loc. Santa Cruz, Ex Coll. C. Darwin," and "55–12–24–143. Loc. Port Desire, Ex Coll. Ch. Darwin," marked as the type of *A.*

canescens. The other is mistakably identified as the type of *A. xanthorhinus*, as already noted under that species.

Akodon canescens is closely related to *A. arenicola* (Waterhouse), based on specimens from Maldonaldo, at the mouth of the La Plata, but it differs from it in smaller size, more grayish coloration, and yellowish muzzle. Two specimens collected by Mr. Durnford at Chubut are referred by Mr. Thomas (*l. c.*) to this species. Mr. Durnford, in his field notes published by Mr. Thomas, says it is "common in straw-heaps and granaries," and that it "burrows in the ground, or more usually takes possession of some of the numerous cracks which may always be found in the earth, and appropriates them for its home. It has five or six young at a birth."

AKODON SUFFUSUS Thomas.

(Plates XI, Fig. 5, Skull; XII, Figs. 9 and 10, Teeth.)

? Hesperomys (*Habrothrix*) *longipilis* Milne-Edwards, Miss. Scient. du Cap Horn, VI, Zoöl., Mamm., 1890, 28, pl. v, fig. 2, animal. "Santa Cruz de Patagonie."

Acodon suffusus Thomas, Ann. and Mag. Nat. Hist. (7), XII, Aug., 1903, 241. "Valle del Lago Blanco, Southern Chubut (Cordillera region)."

Median upper surface, from between the eyes to base of tail, dark dull reddish brown; sides of head and body gray, passing gradually into the reddish brown of the back and into the grayish white of the ventral surface, which extends unusually high up on the sides of the body and cheeks; ventral surface white or grayish white, the pelage plumbeous at the base, in some specimens wholly concealed by the long white tips of the hairs; facial region anterior to the eyes gray like the sides of the body with a faint tinge of brown; ears covered with very short brownish hairs externally, nearly naked internally; tail bicolor, reddish brown above, whitish below, heavily clothed with short hairs; fore feet dingy soiled yellowish gray above, palms naked, flesh color; hind feet soiled whitish, soles naked, dusky brown.

Measurements.—Average and extreme measurements of 13 males: Total length, 170 mm. (165–178); tail vertebræ, 70 (65–74); hind foot, 25 (25–26). The females are slightly larger, 8 females measuring as follows: Total length, 176.6 (170–188); tail vertebræ, 71.8; hind foot, 25.

An average adult skull measures as follows: Total length, 30; basal length, 25; length of nasals, 11; palatal length, 12; palatal foramina,

6.3; diastema, 7.2; upper molars, 4; greatest breadth, 13; interorbital breadth, 5.

This species is represented by 35 specimens, five of which are from the Rio Coy, and the rest, except two from the upper Rio Chico, near or within the Cordilleras, two being from the Pacific slope of the Cordilleras; all were collected by Mr. Peterson. The Rio Coy specimens were taken in November, the Rio Chico specimens at various dates from January 31 to March 4. Two additional specimens were taken by Mr. Colburn, one at Swan Lake, March 14, and the other at the Basalt Cañons, April 30. The several half grown young in the series are similar in coloration to the adults, except that the brown of the upper parts is rather duller. The adults are very uniform in coloration.

In Patagonia this species ranges, as shown by the present material, from the coast region westward into the eastern base of the Andes, and probably thence northward. Mr. Peterson refers to it as one of the most common species of the upper Rio Chico region, frequenting the edge of the timber as well as the more open grassy country. He states that the "skin always adheres to the tail very firmly in adults," and most of the specimens show that the skin of the tail was split open to remove it and afterwards sewed up.

Before the present material came into my hands a number of specimens of this species were sent to Mr. Oldfield Thomas for determination, and he identified them as his *Akodon hirtus*. When at the British Museum in 1901, I made direct comparison of a number of specimens with the type and paratype of *A. hirtus*. In writing up the history of this species in 1902, under the name *Akodon hirtus*, I made the following comment on the case:

"*Akodon hirtus* was based on two specimens collected at San Rafael, Mendoza, by Mr. Bridges many years ago, the type and paratype having been skinned from alcoholic specimens. The skins cannot, therefore, be trusted as regards color; they agree, however, as closely with the upper Rio Chico specimens as could be expected, and the skulls present no appreciable differences. It should be noted, however, that the type locality of the species is about 1,000 miles directly north of the upper Rio Chico region, and it seems more than probable that comparison of a good series of freshly collected skins from the two localities would reveal appreciable differences. The tabulation of the measurements (summarized above) for use in the present connection shows that the dimensions given by Mr.

Thomas for his type of *A. hirtus* are much larger (total length 197) than the very largest of a series of over 20 adults from the Rio Chico country. The measurements of the type skull, however, do not exceed those of average adults from the Rio Chico. For the present I follow Mr. Thomas in identifying the Rio Chico specimens, quite a number of which have passed through his hands, with *A. hirtus*."

Since the above was written, however, Mr. Thomas has described an *Akodon suffusus* from a point quite near the Rio Chico region and in quite similar country, and, in the absence of authentic specimens of *A. suffusus* for comparison, it seems quite beyond question that the present series should be referred to *A. suffusus* rather than to *A. hirtus*, described from a point so much further north and from a markedly different region.

Mr. Thomas, in describing *A. suffusus*, says: "Closely allied to *A. hirtus*, Thos., but the general colour stronger, the belly lighter, and with certain cranial differences detailed below." These are: "Skull in general shape like that of *A. hirtus*, not elongated as in *A. longipilis*. But it is rather lower and flatter throughout, less rounded and convex along the middle line, especially in the interorbital region."

I am also indebted to Mr. Thomas for the suggestion, made some time ago, that *Hesperomys* (*Habrothrix*) *longipilis* of Milne-Edwards, as cited above, is probably his *Akodon hirtus* of later date — now *A. suffusus*.

Subgenus CHELEMYS Thomas.

Chelemys Thomas, Ann. & Mag. Nat. Hist. (7), XII, Aug., 1903, 242.
Type, *Hesperomys megalonyx* Waterhouse.

"General characters, skull, and dentition as in *Akodon*, but the claws, especially the anterior ones, very large, fossorial. . . .

"Now that the known species have been so considerably multiplied, it seems convenient to have a subgeneric name by which to designate what have hitherto been termed the 'long-clawed Akodons.'" — Thomas, *l. c.*

Mr. Thomas formally refers to this subgenus three species, *Akodon megalonyx* (the type), *A. macronyx*, and *A. vestitus*.

AKODON (CHELEMYS) VESTITUS Thomas.

(Plates XI, Fig. 5, Skull; XII, Figs. 9 and 10, Teeth.)

Akodon (*Chelemys*) *vestitus* Thomas, Ann. & Mag. Hist. (7), XII, Aug., 1903, 242, "Valle del Lago, Cordillera region of Southern Chubut Territory, Patagonia."

Adult (February). — Pelage full, soft and long. Above nearly uniform hair brown with a slight yellowish suffusion; sides of head and body and under parts whitish gray, the plumbeous underfur nearly concealed by the long white tips of the hairs; ears small, thickly clothed with short hairs of the color of the dorsal surface; tail short, well clothed, bicolor, brown above and whitish gray below; upper surface of fore and hind feet soiled whitish with a faint tinge of flesh-color, palms and soles naked, the former yellowish flesh-color, the latter similar but slightly darker.

Measurements. — Four adult males measure: Total length, 174 mm.; tail vertebræ, 52; hind foot, 25.5. Three adult females measure: Total length, 174 (168–180); tail vertebræ, 47 (45–50); hind foot, 25.3 (25–26). The longest fore claws have a length of 6 to 7 mm., the longest hind claws measure 4 to 5 mm.

Skull (adult female): Total length, 30; basal length, 26; greatest breadth, 14; interorbital breadth, 5; length of nasals, 12; palatal length, 13; diastema, 8; palatal foramina, 7; upper molars, 5.

This species is represented by 9 specimens taken on the upper Rio Chico, near the Cordilleras, in February, 1897, by Mr. O. A. Peterson. They are all adult and very uniform in coloration, but vary a little in general tone, from yellowish brown to reddish brown.

Its nearest known relative is the *A. macronyx* Thomas, decribed from the "east side of the Andes, near Fort San Rafael, Province of Mendoza," with which Mr. Thomas thus compares it: "General appearance and proportions very much as in *A.* (*C.*) *macronyx* Thos., but colour darker, tail more distinctly bicolor, and skull broader and flatter." He says further: "This species is the southern representative of *A. macronyx* Thos., to which it is no doubt very nearly allied; but the fresh series now available indicates that it should have a name of its own."

Specimens from the Rio Chico, Cordilleras, Patagonia, were sent some years ago by Dr. Merriam to Mr. Thomas for identification, and were labelled by him as "*Akodon macronyx*, Thos." With these specimens before me, I accepted this identification in preparing my account of this species, written two years ago, but added: "The type locality of this species [*A. macronyx*] is near Mendoza, nearly a thousand miles to the northward, and in all probability the southern form here described will prove separable from true *A. macronyx*, at least as a subspecies, on comparison with a good series of Mendoza specimens." Being without ma-

terial for comparison, however, it did not seem desirable to make the separation suggested, and which Mr. Thomas has since made.

Akodon (Chelemys) michaelseni (Matschie).

Hesperomys (*Acodon*) *michaelseni* Matschie, Hamburger Magalhaensische Sammelreise, Säug., 1898, 5, pl. figs. 1, 1 *a–h*, animal, ear, hand and foot, and skull. "Süd. Patagonien, Punta Arenas."—Thomas, Ann. & Mag. Nat. Hist. (7), XII, Aug., 1903, 343 (in text, suggesting it is probably a *Notiomys*).

Adult (January).—Pelage short, thick, soft. Above uniform dusky brown; ventral surface similar but lighter with a slightly grayish instead of brownish hue. Ears short, wholly concealed in the fur; upper surface of fore feet rusty brown; of hind feet dull brown, with a slightly rusty tone. Claws of fore feet very long, as in *A. megalonyx*.

Measurements.—Total length, 142 mm.; head and body, 97; tail, 45; hind foot (without claws), 19; ear, 11. Skull, total length, 27.6; basal length, 24; greatest breadth, 13.4; interorbital breadth, 4.8; length of nasals, 12; palatal length, 11; diastema, 7; palatal foramina, 5.6: upper molar series 3.5. (Measurements from Dr. Matschie, *l. c.*)

Represented by a single specimen, without skull or measurements, of apparently an adult male, taken Jan. 1, 1898, by Mr. Colburn at Punta Arenas, the type locality of the species. In size, proportions, and texture of pelage it closely resembles *Akodon megalonyx*, but differs in its very much darker coloration, both above and below.

Its identity with Dr. Matschie's *Akodon michaelseni*, described and figured from a single female specimen, also taken at Punta Arenas, is almost beyond question, as is also its distinctness from *A. megalonyx*. The species is apparently thus far known only from the specimens here mentioned. It is here referred to the subgenus *Chelemys* with some hesitation. Mr. Thomas (*l. c.*) has recently suggested that it may be referable to *Notiomys*.

Genus NOTIOMYS Thomas.

Notiomys Thomas, in Milne-Edwards, Miss. Scient. du Cap. Horn, VI, Zool., Mamm., 1890, 24. Subgenus of *Hesperomys*. Type, *Hesperomys* (*Notiomys*) *edwardsii* Thomas, sp. nov.—Thomas, P. Z. S., 1896, 1020 (full genus).

The genus *Notiomys* appears to have been based mainly on the character of the feet, notably the presence of strongly developed claws on the fore feet, and the small size of the ears. In remarking upon its affinities Mr. Thomas says:

"Le *Notiomys* offre dans son organisation une combinaison de caractères empruntés à divers sous-genres d'*Hesperomys*. Ainsi, par son aspect extérieur il ressemble aux *Calomys*, par ses griffes allongées aux *Onychomys*, par la griffe dont le pouce est pourvu aux *Scapteromys* et aux *Oxymycterus*. D'autre part, par la structure de son crâne et de ses dents, il se rapproche des *Habrothrix* dont on doit le considérer comme très voisin, malgré les différences extérieures que l'on constate. La nécessité d'établir pour cet animal une distinction subgénérique ne peut être mise en doute et peut-être même, quand on aura pu étudier des exemplaires conservés dans l'esprit-de-vin, reconnaitra-t-on la nécessité de le placer au rang de genre distinct."

Notiomys is more closely related to *Akodon* than to any other genus, it closely approaching the subgenus *Chelemys*, and presenting only a superficial resemblance to either *Oxymycterus* or *Scapteromys*, judging by the description and figures of the only known specimen of *Notiomys*. The skull is rather broad and short, with a broad rostrum, broad and short palatal foramina, and not very heavy dentition, judging by Milne-Edwards's figures (*l. c.*, pl. viii, figs. 1–1*d*),—features quite unlike those found in the smaller species of *Oxymycterus*. The palatal foramina end considerably in front of the first molars, instead of extending posteriorly to about the middle or posterior third of these teeth, as in most species of *Akodon* and *Oxymycterus*, and more resembling the condition commonly seen in *Oryzomys*. The principal characters of *Notiomys* would therefore seem to be the long fore claws, small ears, and short, broad palatine foramina, combined with the usual cranial and dental characters of *Akodon*.

Notiomys edwardsii (Thomas).

Hesperomys (*Notiomys*) *edwardsii* Thomas, in Milne-Edwards, Miss. Scient. du Cap Horn, VI, Zoologie, Mamm., 1890, 24, pl. iii, fig. 1, animal, pl. viii, fig. 1, skull. "Patagonie, au sud de Santa Cruz, vers le 50e degré de latitude Sud."

Notiomys edwardsii Trouessart, Cat. Mamm., ii, 1897, 540, ex Thomas, as above.

Similar in size and general appearance to *Eligmodontia lepida* (Thomas), but easily distinguished by the much larger claws on the fore feet. Above grayish fawn color, below white; tail short, covered with short close hairs, concealing the annulations, pale fawn above and white below. Front feet armed with long, fossorial claws, similar to those of *Akodon* (*Chelemys*) *macronyx;* claws of hind feet rather long; soles naked, flesh-color; ears small.

Measurements.—Total length, 115 mm.; head and body, 80; tail vertebræ, 35. Skull, total length, 20; greatest breadth, 13; length of nasals, 9.7; palatal length, 11; diastema, 6.1; upper molar series, 3.2. Description abridged from Thomas (*l. c.*).

This small species appears to be still known only from the unique type, collected by Mr. Lebrun, a little southward of Santa Cruz (lat. 50° S.), Patagonia. It is not included in the very large series of Muridæ collected near the type locality by the Princeton Expeditions, and it is therefore probably not numerously represented.

Genus OXYMYCTERUS Waterhouse.

Oxymycterus Waterhouse, P. Z. S., 1837, 21. Subgenus of *Mus*. Type, *Mus* (*Oxymycterus*) *nasutus* Waterhouse.—Tomes, P. Z. S., 1861, 285 (full genus).—Thomas, P. Z. S., 1884, 450 (subgenus of *Hesperomys*); P. Z. S., 1896, 308 (full genus).

The chief characters of *Oxymycterus* are the long narrow rostrum, relatively narrow interorbital region with evenly rounded supraorbital edges, the maxillary branch of the zygoma narrow with its antero-superior border rounded, fossorial claws, and small ears. There is nothing very characteristic in the structure of the molars to distinguish it from *Akodon* and allied genera.

The group contains at present some 15 to 20 species, ranging from the Andean region eastward and southward over southern Brazil to Patagonia. They vary greatly in size, and somewhat in other features. Thus *O. lanosus* is but little larger than a house mouse, while *O. inca*, *O. juliacæ* and *O. apicalis* are as large as a half-grown house rat, with other species intermediate in size. The whole dentition, incisors as well as molars, is weak in all, but in the smaller species is apparently even more reduced than in the larger forms, but the maxillary branch of the zygoma is relatively broader and less rounded on the upper anterior border than in the

larger forms. *O. apicalis* is an aberrant member of the group, as regards its external characters, having non-fossorial claws and peculiar pelage.

The present collection includes two species referable to *Oxymycterus*, namely, *O. lanosus* Thomas and *O. microtis* Allen. They are both small forms, with fossorial claws and small ears, with the teeth and general form of the skull of the larger species of *Oxymycterus*, but with very small teeth and a relatively wider and less rounded zygomatic plate. The single skull of *O. lanosus* (the specimen was identified by Mr. Oldfield Thomas) has no trace of an interparietal, which would thus seem to ally it with *Blarinomys*.

In the accompanying plates (Pl. IX, Figs. 3–6, Pl. X, Figs. 6–10), the skull and dentition is presented, for convenience of comparison, of five species of *Oxymycterus*, including such diverse forms, as *O. lanosus*, *O. microtis*, *O. inca*, *O. juliacæ* and *O. apicalis*.

Oxymycterus lanosus Thomas.

Hesperomys (*Habrothorix*) *xanthorhinus* Thomas, P. Z. S., 1881, 5, part; only the specimen from Monteith Bay.

Oxymycterus lanosus Thomas, Ann. & Mag. Nat. Hist. (6), XX, Aug., 1897, 218. Monteith Bay, Straits of Magellan.

Adult (February).—With a striking similarity to *Akodon xanthorhinus* in size, proportions and coloration, but with much smaller ears, and softer and much thicker pelage. Color above deep yellowish brown, varied with blackish; below grayish white; nose not yellowish as in the *A. xanthorhinus* group; upper surface of feet soiled yellowish white; tail bicolor, brownish above, whitish gray below; ears small, slightly overtopping the fur, scarcely different in coloration from the surrounding pelage.

Measurements.—Adult male: Total length, 127 mm.; tail vertebræ (mutilated in life), 40; hind foot 20. Adult female: Total length, 145; tail vertebræ, 55; hind foot 20. Skull, adult female: Total length, 24.6; basal length, 21; greatest breadth, 11.8; interorbital breadth, 4; length of nasals, 10; palatal length, 9.5; diastema, 6; palatal foramina, 5.2; upper molar series, 3.5. There is no interparietal.

This species is represented by only two specimens, collected on the upper Rio Chico de Santa Cruz, in the Cordilleras, by Mr. Peterson, Feb. 10, 1897. Both specimens have been identified as this species by Mr.

Thomas, the type locality of which is Monteith Bay, Straits of Magellan. Not compared by me with the type.

Mr. Peterson's notes state that both specimens, a pair, were caught together "in heavy grass and brush, near a small brook."

This species, if properly referable to *Oxymycterus*, is the smallest member of the genus, so far as at present known, being considerably smaller even than *O. microtis*.

Oxymycterus microtis Allen.

(Plates IX, Fig. 4, Skull; X, Fig. 7, Teeth.)

Oxymycterus microtis Allen, Bull. Am. Mus. Nat. Hist., XIX, 189, May 9, 1903. Pacific slope of Cordilleras, upper Rio Chico de Santa Cruz, Patagonia. — Thomas, Ann. & Mag. Nat. Hist. (7), XII, Aug., 1903, 243 (in text, suggesting its reference to *Notiomys*).

Adult male (type), March. — Pelage thick, short, and fine, almost mole-like in character. Pelage and general color almost exactly as in *Oxymycterus lanosus* Thomas, but twice the size of that species, with tail one half shorter and fore claws large, fossorial. Above dark yellowish brown; underparts whitish gray, the plumbeous underfur tinging the otherwise whitish surface; top and sides of nose dark grayish brown, without any tinge of yellow or rufous; ears very small, scarcely reaching the surface of the short fur, concolorous with the enclosing fur; tail very short, but little exceeding the length of the hind foot, very thickly clothed, dark brown, only slightly lighter below than above; upper surface of feet grayish brown, the toes lighter, yellowish white; soles naked, dark flesh-color.

A second spceimen is exactly similar in coloration, except that the ventral surface has a slight wash of buff, apparently due to staining.

Measurements. — Total length (type), 138 mm.; tail vertebræ, 28; hind foot, 21; longest fore claw, 6. Skull, total length, 27.6; basal length, 23.6; zygomatic breadth, 12.5; width of brain case, 12; interorbital breadth, 5; length of nasals, 10.5; palatal length, 10; palatal foramina, 5; diastema, 6.3; upper molar series, 3.5; length of lower jaw (inner base of incisors to posterior border of condyle), 15; height at condyle, 5.5; lower molar series, 3.4.

Represented by two specimens — a skin and skull, and a skin and skeleton — collected on the Pacific Slope of the Cordilleras, at the head of the Rio Chico de Santa Cruz.

Externally *Oxymycterus microtis* is a miniature of *Akodon macronyx* with a relatively much shorter tail. It exactly resembles in coloration above and in the texture of the pelage *Oxymycterus lanosus*, but the latter has whiter under parts, is very much smaller, has a much longer tail, and small, non-fossorial claws; but the skulls of the two are very similar in general contour, differing only in size and slightly in details. *O. microtis* thus combines the large fossorial claws of the *Akodon* (*Chelemys*) *macronyx* group with the cranial characters and weak dentition of the *O. lanosus* type. The narrow line separating *Akodon* and *Oxymycterus* is thus still further narrowed by the present annectent link.

Since the foregoing description was published Mr. Oldfield Thomas (*l. c.*) has expressed the opinion that, "From the descriptions given it seems not impossible that both '*Hesperomys* (*Acodon*) *Michaelseni*,' Matchie, and '*Oxymycterus microtis*,' Allen, belong to *Notiomys*, as their long claws, short tails, and very small molars agree precisely with what is found in that group." With the skull and skins of *O. micropus* before me, however, I see no reason for not viewing the species as far better referable to *Oxymycterus* than to *Notiomys*, judging *Notiomys* by the published figures of the species, including the skull.

Order FERÆ.

Suborder PINNIPEDIA.

Family *PHOCIDÆ*.

The Phocids or Earless Seals are represented in the southern hemisphere by five species, referable to as many genera, of which three have been recorded from the Straits of Magellan, the coast of Patagonia, or the Falkland Islands, and hence come within the limits of the present treatise. These are the Leopard Seal (*Hydrurga leptonyx*), Weddell's Seal (*Leptonychotes weddellii*), and the Sea Elephant (*Mirounga leoninus*). There is also a record of the capture of several examples of the Crab-eating Seal (*Lobodon carcinophaga*) near San Isidro, a few miles north of the city of Buenos Aires;[1] but otherwise than this both this species and Ross's Seal (*Ommatophoca rossii*) are known only from the vicinity of the pack-ice of the antarctic seas. Although the occurrence of *Lobodon*

[1] Berg, Com. Mus. Buenos Aires, I, 1898, p. 15.

carcinophaga in the Rio de la Plata must have been entirely fortuitous, this species is here included, since its capture there in several instances implies its occasional occurrence on the coast of Patagonia.

Genus HYDRURGA Gistel.

Stenorhinque F. Cuvier, Mém. du Mus., XI, 1824, 190.

Stenorhinchus F. Cuvier, Dict. des Sci. Nat., XXXIX, 1826, 549. Type and only species, *Phoca leptonyx* Blainville.

Stenorhyncus F. Cuvier, Dict. des Sci. Nat., LIX, 1829, 463 (same as above).

Stenorhynchus Lesson, Man. Mamm., 1827, 199.

Stenorhincus McMurtrie, Cuvier's An. Kingd., abr. ed., 1834, 71.

"*Hydrurga* Gistel, Naturg. Thierreichs, 1848, p. xi."—T. S. Palmer, Science, n. ser., X, No. 249, Oct. 6, 1899, 494; Index Gen. Mamm., 1904, 337.

Ogmorhinus Peters, Monatsb. Akad. Berlin, 1875, 393, footnote. New name for *Stenorhynchus*, preoccupied in carcinology and entomology.

Stenorhynchotes Turner, Zoöl. Challenger Exp., pt. lxviii, 1888, 63, footnote. Not adopted, but mentioned as a modification of *Stenorhynchus* that could have been advantageously adopted in place of *Ogmorhinus*.

As has long been known, the generic name *Stenorhinchus* F. Cuvier, 1826, modified by Lesson in 1827 to *Stenorhynchus*, and by its proposer, in 1829, to *Stenorhyncus*, is preoccupied by *Stenorhynchus* Lamark, 1818, for a genus of Crustacea, and again in 1823, and still again in 1825, for different genera of insects. On this account Peters in 1875 proposed to replace it with *Ogmorhinus*. But there appears to have been already an earlier name than *Ogmorhinus*, as recently shown by Palmer, namely, *Hydrurga* Gistel, 1848, which should of course be adopted in place of *Ogmorhinus*.

HYDRURGA LEPTONYX (Blainville).

Sea lion from islands Falckland, Blainville, Journ. de Phys., XCI, Oct., 1820, 287, 288. Description of a skull in Museum of College of Surgeons, London, labelled as having come from "iles Falckland."

Phoca leptonyx Blainville, *ibid.*, 297, 298, fig. 5 of pl. published Dec., 1820. Stuffed specimen in collection of "M. Hauville, au Havre,"

with the same dentition as the skull described on pp. 287, 288. Also said to have come from the "environs des îles Falckland ou Malouines."

Phoca leptonyx Desmarest, Mamm., I, 1820, 247 (ex Blainville). See also note on p. 243, under *Phoca leporina*.—G. Cuvier, Ossem. foss., V, i, 1823, 207, pl. xviii, fig. 2. Same specimen.

Seal from New Georgia, Home, Philos. Trans., 1822, pt. i, 240, pl. xxix, skull; Lect. Comp. Anat., III, 1823, 118; IV, 1823, pl. xx, skull. The same skull described by Blainville, as coming from the Falkland Islands, but here said to have come from the Island of New Georgia.

Stenorhinchus leptonyx F. Cuvier, Dict. des Sci. Nat., XXXIX, 1826, 549. "Iles Malouines et de la Nouvelle-Géorgie." From Blainville and Home.

Stenorhynchus leptonyx Lesson, Man. Mamm., 1820, 199.—Nilsson, Arch. f. Naturg., 1841, pt. i, 307.—Owen, Ann. & Mag. Nat. Hist., XII, 1843, 232.—Gray, Zoöl. Erebus and Terror, Mamm., 1844, 6, pl. iii, animal, pl. iv, skull; Cat. Seals and Whales Brit. Mus., 1866, 16; and in his subsequent papers.—Jacquinot & Pucheran, Voy. au Pole Sud, Zool., III, Mamm. et Ois., 1853, 27, "terres australes, au sud-est du cap Horn"; Atlas, 1842–1853 (circa 1842), pl. ix, animal and skull.—Abbott, P. Z. S., 1868, 192 (Falkland Islands).—Sclater, *ibid.*, p. 192, footnote, and p. 527 (Falkland Islands).—Cunningham, Nat. Hist. Strait Magellan, 1871, 182. Magellan Strait.—Flower, Cat. Osteol. Coll. Roy. Coll. Surgeons, II, 1884, 211. Tasmania, New Zealand, Falkland Islands, New Georgia (includes the Blainville and Home specimen).—Borchgrevinck, First on Antarctic Continent, 1901, 65, 170, 230, 236, near Victoria Land.

Ogmorhinus leptonyx Peters, Monatsb. Akad. Berlin, 1875, 393.—Allen, N. Am. Pinnipeds, 1880, 466.—Turner, Zoöl. Challenger Exp., pt. lxviii, 1888, 64.—Barrett-Hamilton, Rep. Southern Cross Coll., 1902, 23–34, exhaustive general account.—Wilson, *ibid.*, 71–73, distribution and habits.—Bruce, Proc. Phys. Soc. Edinb., XII, 1892–1894 (1894), 380, near Graham Land; Rep. 63d Meet. Brit. Assoc., 1893 (1894), 807.—Bernacchi, To South Polar Regions, 1901, 319, 325, with text cuts of animal, from life.

Ogmorhynus leptonyx Cook, First Antarctic Night, 1901, 256, 281, 383, animal, from photographs.

Phoca homei Lesson, Dict. class. d'Hist. Nat., XIII, 1828, 417. New name for *Phoca leptonyx* Blainville.

Hydrurga leptonyx R. J. P[ocock], Rep. Southern Cross Coll., 1902, 26 (footnote).

This species is unrepresented in the collections made by the Princeton University Expeditions to Patagonia, but it has been repeatedly recorded from the Falkland Islands. Dr. Sclater (P. Z. S., 1868, 527) states that Mr. A. A. Lecompte shot, in 1867, "a single Sea Leopard (*Stenorhynchus leptonyx*) in a remote part of Stanley Harbour, being the only specimen of this animal met with during his stay in the Falklands." Captain C. C. Abbott (*l. c.*, p. 192), during his residence there, met only a single specimen, "washed ashore dead near Port Louis." Mr. Barrett-Hamilton also records two skulls in the British Museum taken on the Falkland Islands, in the list of specimens given by him in his paper on the Mammalia of the *Southern Cross* Collections (pp. 32, 33).

The several recent South Polar expeditions report this seal as found in some frequency on the pack-ice near Graham Land and Victoria Land, where it is the most numerous of the several species found in these high latitudes. It has been taken also at New Georgia and on the shores of New Zealand.

The type locality of *Phoca leptonyx* Blainville may be considered as somewhat in doubt, as it is evident that the specimen described (*l. c.*, pp. 297, 298) in connection with the bestowal of the name (on p. 298) must be considered as the type, rather than Blainville's specimen No. 2 ("2°. Sea lion from islands Falckland"), described on pages 287 and 288. The former — the type specimen — he says "à été rapportée des mers du sud, et, à ce qu'il paroit, des environs des îles Falckland ou Malouines." The other specimen, belonging to the "college des chirurgiens à Londres," and labelled as from the Falkland Islands, was, two years later, described and figured by Home (*l. c.*) as a "Seal from New Georgia," which place appears to have been the correct locality of the specimen.[1] It is apparently, therefore, fair to assume the Falkland Islands as the type locality rather than the Island of New Georgia.

The history of this seal is very fully given by Mr. Barrett-Hamilton in

[1] On this point see Barrett-Hamilton, who has gone into the history of these two important specimens in considerable detail in his Report on the Mammalia of the *Southern Cross* Expedition (pp. 26, 27).

his report on the Mammalia of the *Southern Cross* Collections, including its bibliography, distribution, habits, external appearance, and cranial characters, which is admirably supplemented in the same work by Mr. Wilson's summary of recent observations of the animal in life, based on the accounts of the various explorers who have met with it in the pack-ice of the Antarctic.

Genus LEPTONYCHOTES Gill.

Leptonyx Gray, Charlesworth's Mag. Nat. Hist., I, Nov., 1837, 582. Type, *Otaria weddelli* Lesson. Preoccupied in ornithology.

Leptonychotes Gill, Arrang. Fam. Mamm., 1872, 70. New name for *Leptonyx* Gray, preoccupied.—Allen, N. Amer. Pinn., 1880, 418, 463, 467.—Turner, Zoöl. Challenger Exped., pt. lxviii, 1888, 20.—Barrett-Hamilton, Rep. Southern Cross Coll., 1902, 17.

Pœcilophoca Flower & Lydekker, Mamm. Liv. and Ext., 1891, 605. New name for *Leptonyx* Gray, preoccupied = *Leptonychotes* Gill, 1872.

This genus was made known by Gray in 1837, on the basis of specimens obtained by Captain Fitzroy on the coast of Patagonia, more fully described and figured in 1844, in the "Zoölogy of the Erebus and Terror," but he unfortunately adopted for it the preoccupied name *Leptonyx*, replaced by Gill in 1872 by *Leptonychotes*, and again in 1891 by *Pœcilophoca* proposed by Flower and Lydekker, apparently in ignorance of *Leptonychotes* Gill.

LEPTONYCHOTES WEDDELLII (Lesson).

Sea Leopard Weddell, Voy. towards the South Pole, 1825, 22, with plate of animal entitled "Sea Leopard of South Orkneys."

Otaria weddellii Lesson, Férussac's Bull. Sci. Nat., VII, 1826, 437, 438. Based on the Sea Leopard of Weddell, as above (name spelled *Otaria weddelii* on p. 438).

Stenorhyncus weddellii Lesson, Man. de Mamm., 1827, 200.

Stenorhynchus weddellii Owen, Ann. & Mag. Nat. Hist., XII, 1843, 332.—Gill, Proc. Essex Inst., V, 1866, 6.

Leptonyx weddellii Gray, Charlesworth's Mag. Nat. Hist., I, Nov., 1837, 582; List Mamm. Brit. Mus., 1843, 102; Zoöl. Erebus and Terror, Mamm., 1844, 7, pl. v, animal, pl. vi, skull. Santa Cruz River, east coast of Patagonia, Capt. Fitzroy. Also of Gray's later papers and works on Seals.—Hatcher, Narrative, 1903, 77. Corriken Aike.

Leptonychotes weddellii Allen, N. Amer. Pinnipeds, 1880, 467. — Turner, Zoöl. Challenger Exp., pt. lxviii, 1888, 20. Betsey Cove, Kerguelen. — Cook, First Antarctic Night, 1901, 265, 281, 283, animal, from photographs. — Albert, Act. Soc. scient. du Chili, XI, Dec., 1901, 221 (casual at Juan Fernandez and Mocha Islands). — Barrett-Hamilton, Rep. Southern Cross Coll., 1902, 17–23, monographic. — Wilson, *ibid.*, 69–71, distribution and habits.

P[œcilophoca] weddelli Flower & Lydekker, Mam. Liv. and Ext., 1891, 605.

Leptonyx leopardinus Wagner, Schreber's Säug. Suppl., VII, 1846, 38.

Stenorhynchus leptonyx Moseley, Notes by a Naturalist, etc., 1879 (in error, *apud* Barrett-Hamilton). Kerguelen Island.

Leopardine Seal, Jameson, in Weddell's Voy. towards the South Pole, 1823, 23, 134.

Phoca leopardina Hamilton, Amphib. Carn. in Jardine's Nat. Library, VI, 1839, 183, and on pl. xii and in table of contents. Attributed to Jameson and = Leopardine Seal of Jameson, as above.

This species is unrepresented in the material at present available for examination from Patagonia, but Hatcher speaks of it as common off the coast at Corriken Aike. The earliest record of its occurrence in Patagonia is Gray's reference in 1843 to the specimens obtained by Capt. Fitzroy at the mouth of the Santa Cruz River, on the east coast of Patagonia in his "List of the Specimens of Mammalia in the British Museum" (1843, p. 102), and in the "Zoölogy of the Erebus and Terror" (Mamm., 1844, p. 7, and figured in plates v and vi).

Mr. Hatcher thus refers to its presence in numbers off Corriken Aike in September and October, 1896: "On quiet days, when the tides were running at their highest, the waters immediately fronting the shingle-covered beach were frequented by considerable numbers of *Leptonyx weddeli*, the common haired seal or sea leopard of this region. Occasionally these animals would approach quite near the beach, just beneath where we were engaged with our fossils, and thrusting their heads far out of the water remain stationary for a moment, apparently intent on ascertaining the meaning of our presence." (Narrative, p. 77.)

According to Albert (*l. c.*), a specimen was taken at Juan Fernandes Island in 1865, and the species is seen every two or three years about Mocha Island, coast of Chili.

Mr. Wilson (*l. c.*, p. 69) states that Weddell's Seal is a shore seal, and

is not met with in the ice-pack. It ranges, however, very far south, being found, he says, "in great numbers on the coast of South Victoria Land, and is the species most commonly met with in Ross's Sea. At almost the farthest southern point reached by the *Southern Cross* Expedition these seals were numerous, and even in a piece of water south of the edge of the Great Barrier, which apparently communicated under ice with the sea, a number of them were found. . . .

"Weddell's Seal was the only species found breeding in any considerable numbers by the *Southern Cross* Expedition. Some dead young seals were found buried in guano at Camp Ridley on Cape Adare, but apparently no Weddell's Seals breed there now, though in Robertson Bay, close by, a large number of them were breeding, and many young were born." The date of the birth of the young is given as September.

The species was first named by Lesson in 1826, his account being based entirely on the description (by Professor Jameson) and drawing published by Captain Weddell, the previous year, in his "Voyage towards the South Pole" (p. 22). Professor Jameson's description is as follows: "Leopardine seal, the neck long and tapering; the head small; the body pale-greyish above, yellowish below, and back spotted with pale white. This species to be referred to the division Stenorhinque, of F. Cuvier; the teeth, however, do not quite agree with those of his Phoque Septonyx [sic], nor with those of Sir E. Home, in pl. xxix of the Philosophical Transactions for 1822."

Yet Lesson, believing that it had small ears which had been omitted by error in the drawing, referred it to the genus *Otaria*, but afterwards (1827) to the genus *Stenorhyncus*. Weddell brought home an "excellent specimen," which he presented to the Edinburgh Royal Museum, and which was later described in Dr. Robert Hamilton's "Amphibious Carnivora" (Jardine's Naturalist's Library, Vol. VI, 1839, pp. 183–187, pl. xii). This specimen evidently came from the South Orkneys (latitude 60° 37′ S.), where Captain Weddell says his men killed quite a number of the animals, and that he saw others off the South Shetlands. This specimen, according to Barrett-Hamilton (*l. c.*) is now in the new Edinburgh Museum of Science and Art.

Gray, in 1837, gave the first intelligible description of the species, from two specimens, skins and skulls, obtained by Captain Fitzroy at the mouth of the Santa Cruz River, on the coast of Patagonia, but he gave the

locality simply as the "Southern seas." In the Zoölogy of the *Erebus* and *Terror* he redescribed these specimens in greater detail, adding the locality of capture, and giving figures of both the animal and skull. In both these accounts he adopted the specific name appropriately given it by Lesson, and by which it has since been uniformly known, except in one or two instances of inadvertence. The only synonym, and one which has never had currency, is the *Phoca leopardina* of Hamilton, who thus rendered the "Leopardine Seal" of Jameson, contained in an inedited contribution to Weddell's "Voyage," and wrongly attributed the name to Jameson.

Genus LOBODON Gray.

Lobodon Gray, Zoöl. Voy. Erebus and Terror, Mamm., 1844, 5. Type and only species, *Phoca carcinophaga* Jacquinot & Pucheran.

LOBODON CARCINOPHAGA (Jacq. & Puch.).

Phoca carcinophaga Jacquinot & Pucheran, Voy. au Pole Sud, Atlas, Mamm., 1842 (circa), pl. x, animal, pl. x*a*, skull. No description. South polar seas, "entre les îsles Sandwich et les îsles Powels."

Lobodon carcinophaga Gray, Zoöl. Voy. Erebus and Terror, Mamm., 1844, 5, pl. i (animal), pl. ii (skull); Cat. Seals Brit. Mus., 1850, 10; and of Gray's subsequent works and papers. — Jacquinot & Pucheran, Voy. au Pole Sud, Zool., III, 1853, 27–30. — Allen, N. Amer. Pinnipeds, 1880, 466. — Cook, First Antarctic Night, 1901, 256, 281, cuts from photographs. — Barrett-Hamilton, Rep. Southern Cross Coll., 1902, 35–45, monographic. — Wilson, *ibid.*, 74–76, habits and distribution. — Berg, Com. Mus. Buenos Aires, I, No. 1, Aug., 1898, 15. Accidental in Rio de la Plata.

Stenorhynchus carcinophagus Flower, Cat. Osteol. Vertebr. Anim. Mus. College Surgeons, III, 1884, 213.

Ogmorhinus carcinophagus Turner, Zoöl. Challenger Exped., XXVI, pt. lxviii, 1888, 64.

Stenorhynchus serridens Owen, Ann. & Mag. Nat. Hist., XII., Nov., 1843, 332.

This species was first made known through the publication of Jacquinot and Pucheran's plates of mammals in the Atlas of the Zoölogy of the "Voyage au Pole Sud et dans l'Oceanie," which appeared at various dates between 1842 and 1853. Plates 10 and 10*a* carry the name *Phoca car-*

cinophaga, the first giving a view of the animal, the other excellent figures of the skull and teeth. The exact date of their publication is in doubt, but they must have appeared in 1842 or early in 1843, as they are cited by Gray in 1844, in the Zoölogy of the *Erebus* and *Terror*, where he claims priority for Jacquinot and Pucheran's name over *Stenorhynchus serridens* Owen, published in the "Annals and Magazine of Natural History" for November, 1843.

The Crab-eating Seal is one of the most common of the seals found in the pack-ice of the Antarctic regions, outside of which, so far as known, it is rarely seen. There is no record of its appearance in the Tierra del Fuego Archipelago, nor on the shores of Patagonia, but it has found its way on two or three occasions, as recorded by Berg,[1] to the Rio de la Plata, near Puerto de Ensenada and San Isidro, in latitude about 34°30′ south. Its more or less frequent occurrence on the coast of Patagonia seems, therefore, more or less probable. Its casual straggling to the mouth of the La Plata is somewhat parallel to the occurrence of the Crested Seal (*Cystophora cristata*) in Long Island Sound and on the coast of France, and the Harbor Seal (*Phoca vitulina*) on the coast of North Carolina, 300 to 500 miles south of their normal southern limit.

Its history, so far as known, is very fully detailed by Barrett-Hamilton, who gives (*l. c.*, pp. 35–45) its bibliography, synonymy, distribution, habits and external and cranial characters, based on the examination of a large number of specimens obtained by the *Southern Cross* expedition, the Belgian Antarctic expedition, and Ross's Antarctic expedition of 1839–43. This is supplemented by Wilson's further notes (*l. c.*, pp. 74–76) on its habits and distribution.

[1] Mr. Berg's account is so short and of so much interest that it is here transcribed in full:

"*Lobodon carcinophagus* (H. J.) Gr. en el Río de la Plata. — Esta foca, que habita la región antártica, aparece en aislados casos también en regiones más septentrionales. Así, por ejemplo, menciona el Dr. Burmeister en su "Atlas de la description physique de la République Argentine. II. Die Seehunde der Argentinischen Küsten" (1883), haber visto el cráneo de uno de estos pinipedios que había llegado vivo al Rio Santo Cruz (φ 50°), sobre un témpano de hielo.

"Más digno aún de mención es el hecho de haberse encontrado un ejemplar de esta especie en el Río de La Plata, cerca del Puerto de Ensenada, que se conserva en el Museo de La Plata, y otro en la proximidad de San Isidro, al norte de Buenos Aires (φ 34°28), en el mes de Junio del año corrinete, que se encuentra actualmente en nuestro Museo.

"Este último ejemplar, un macho mide 2 metros y 65 centimetros, y es de color blanco impuro, presentando algunas manchas irregulares amarillentas y poco definidas, que no fueron notadas en el animal antes del embalsamamiento."—C. Berg, in Comunicaciones del Museo nacional de Buenos Aires, Tomo I, No. 1, 24 de Augusto de 1898, p. 15.

Genus MIROUNGA Gray.

Macrorhine F. Cuvier, Mém. du Mus., XI, 1824, 200, pl. xiii, fig. 2, *d*, *e*, *f*. Type, *Phoca proboscidea* Péron = *Phoca leonina* Linn.

Machrorhinus F. Cuvier, Dict. des Sci. Nat., XXXIX, 1826, 552; LIX, 1829, 464 = *Macrorhine*, F. Cuvier, 1824. Preoccupied by *Macrorhinus* Latreille, 1825, for a genus of Coleoptera.

Macrorhyna Gray, Griffith's An. King., I, 1827, 180 (err. typ. for *Macrorhinus*, *apud* Gray, Cat. Seals, 1850, 34).

Mirounga Gray, Griffith's An. King., V, 1827, 179 (in part). Type, by elimination, *Phoca proboscidea* Péron.

Morunga Gray, Zoöl. Voy. Erebus and Terror, Mamm., 1844, 4; List Osteol. Spec. Br. Mus., 1847, 33. An emendation of *Mirounga* and restricted to *Phoca proboscidea* Péron.

Rhinophora Wagler, Nat. Syst. Amphib., 1830, 27. Type, *Phoca proboscidea* Péron.

Cystophora Nilsson, Vet. Akad. Hand., 1837, —; Arch. f. Naturg., 1841, i, 323 (in part; not of Nilsson, 1820, when *Cystophora* included only *Phoca cristata* Erxl.). Also of Peters, in part.

Physorhinus Gloger, Hand- u. Hilfsbuch der Naturg., 1841, 163. Type, *Phoca proboscidea* Péron.

The Sea Elephant was removed from the genus *Phoca* in 1824 by F. Cuvier as the type of a special genus to which he applied the French term Macrorhine, which he first used in its proper techinal form, *Macrorhinus*, in 1826 for the same group. In the meantime (1825) Latreille gave the same name to a genus of coleopterous insects. According to present usage the name Macrorhine is untenable, and its technical equivalent is preoccupied by one year by Latreille's *Macrorhinus*.

In 1827 Gray proposed the genus *Mirounga*, to include the Sea Elephant and Hooded Seal, which latter had already been made the type of the genus *Cystophora* by Nilsson in 1820. The type of *Mirounga* would thus become, by restriction, the Sea Elephant, to which Gray himself, in 1847, restricted the name, at the same time emending it to *Morunga*. In 1830 Wagler proposed the genus *Rhinophoca*, with *Phoca proboscidea* Péron as the type and only species. Gloger in 1841 again renamed the genus *Physorhinus*.

From the foregoing it is evident that the proper name of the Sea Elephant group is *Mirounga* Gray, 1827.

MIROUNGA LEONINA (Linnæus).

Sea-lyon Anson, Voy. round the World, 1748, 122, pl. entitled "A Sea-Lion and Lioness," Island of Juan Fernandez.

Skull of Seal brought by Lord Anson from Southern Seas, Home, Comp. Anat., IV, 1823, pl. xviii. See also Nilsson, Arch. f. Naturg., 1841, i, 324; Flower, P. Z. S., 1881, 146; Cat. Osteol. Coll. Mus. Roy. Coll. Surgeons, II, Mamm., 1884.

Phoca leonina Linn., Syst. Nat., 1758, 37. Based exclusively on the "Sea-lyon" of Anson.

Loup marin Pernetty, Voy. aux Iles Malouines, II, 1769, 447, 561, pl. ix*. Figure copied from Anson, slightly altered.

Phoca leonina Schreber, Säug., III, 1776, 297, pl. lxxxiii*a*. Based on the above. Plate after Anson. — Shaw, Gen. Zoöl., I, 1800, 268, pl. lxxiii, after Anson.

Macrorhinus leoninus Allen, N. Am. Pinnipeds, 1880, 466 (synonomy and distribution); Fur Seal Arbitra., Case of United States, 1892, 388, economic history. — Flower, P. Z. S., 1881, 145–162 (Falkland Islands, skull and dentition, etc.); Cat. Osteol. Coll. Roy. Coll. Surgeons, II, 1884, 215. — Turner, Zoöl. Challenger Exp., pt. lxviii, 1888, 3–19, pls. i–iv. Kerguelen and Heard Islands; external characters and osteology. — Albert, Act. Soc. scient. du Chili, XI, Dec., 1901, 217–220. Synonymy, description, history, habits, products, etc.

Phoca elephantina Molina, Sag. Stor. Nat. Chili, 1782, 260. New name intentionally given for *Phoca leonina* Linn.

Morunga elephantina Gray, Zoöl. Erebus and Terror, Mamm., 1844, 4, 8, pl. ix, animal, female, pl. x, skull, female; Cat. Seals and Whales, 1866, 38, fig. 13, skull. Also of Gray's various later works.

? Phoca porcina Molina, Sag. Stor. Nat. Chili, 1782, 279 (young).

Phoca proboscidea Péron, Voy. aux Terres. Austr., II, 1816, 34 (32–66), pl. xxiii, animal. — Desmarest, Nouv. Dict. d'Hist. Nat., XXV, 1817, 550, pl. G44, fig. 2, animal; Mamm., I, 1820, 238.

Mirounga proboscidea Gray, Griffith's An. King., V, 1827, 180.

Morunga proboscidea Sclater, P. Z. S., 1868, 227. Falkland Islands (nearly extinct).

Cystophora proboscidea Nilsson, Vet. Akad. Hand., 1837, ——; Arch. f. Naturg., 1841, i, 323. With important critical and historical comment.

Sea Elephant, Weddell, Voy. towards the South Pole, 1825, 134–137. South Shetlands; habits, and destruction for oil.

So far as the evidence has been presented, there seems to be no good reason for recognizing more than a single species of Sea Elephant in the southern seas, with which the California Sea Elephant is so closely related as to have been considered by some authors as doubtfully distinct from the southern species. Three names have been, at one time or another, more or less current for the species, as shown by the above citations, namely, *leonina* (*Phoca leonina* Linn., 1758), *elephantina* (*Phoca elephantina* Molina, 1782), and *proboscidea* (*Phoca proboscidea* Péron, 1816). The type locality of *Phoca leonina* is Juan Fernandez Island, and of *Phoca elephantina* the coast of Chili, including the Juan Fernandez Islands, the name having been proposed as a substitute for *Phoca leonina*. Péron gave the name *Phoca proboscidea* to the Sea Elephant of the southern seas at large. *Phoca resima* of the same author has special reference to the Sea Elephant "des St.-Pierre et St.-Paul d' Amsterdam (*Phoca Resima*, N.) dont MaCartney, Cox et Mortimer nous ont successivement donné l'intéressante his-

toire," afterwards renamed *Phoca coxii* by Desmarest. In 1875 Peters proposed to call the Falkland Islands animal, the Loup marin of Pernetty, *Cystophora falklandica*, and the Kerguelen animal *Cystophora kerguelensis*. In this connection Peters recognized five species of Sea Elephant, as follows: 1, *Cystophora leonina* (Linn.); 2, *C. falklandica*, sp. nov., Sea Lion of Pernetty; 3, *C. proboscidea* (Péron); 4, *C. angustirostris* (Gill), California Sea Elephant; 5, *C. kerguelensis*, sp. nov., The two new names are given in a footnote, without indication of any distinctive characters, the record merely expressing the author's opinion respecting probable species of Sea Elephants. Subsequent writers have almost unanimously referred all of the Sea Elephants of the southern hemisphere to a single species, *leonina* Linn.[1]

Geographical Distribution. — "Sea-elephants were formerly found in great abundance at nearly all of the Oceanic Islands south of the thirtieth parallel of south latitude. Kerguelen Land and Heard Island were especially favorite resorts for them. They were also abundant at the Falkland Islands, Staten Land, South Georgia, throughout the Tierra del Fuego Archipelago, on the coasts of Patagonia, and as far north on the Pacific coast of South America as Mas-à-Fuero and Juan Fernandez. They also occurred in large numbers at the Tristan d'Acunha group, the Crozets, the Prince Edward Islands, St. Paul and Amsterdam Islands, the coasts and islands of southern Australia and New Zealand, and the numerous islands to the southward and eastward of New Zealand. At most of these points, however, they became long since practically exterminated, though still occurring at Kerguelen Land, Heard Island, and at a few other points in sufficient numbers to render sea-elephant hunting attractive to the few sealers and whalers who still frequent these waters.[2]

"History of Sea-Elephant Hunting. — Sea-elephant hunting began early in the present century, and for years, either exclusively or in conjunction with whaling, proved a lucrative employment, largely monopolized by Americans. From the incomplete statistics at hand, sea-elephant hunt-

[1] "The evidence upon which Dr. Peters has based four supposed species of southern Elephant Seal, viz., *leonina*, *falklandica*, *proboscidea*, and *kerguelensis*, is still more shadowy; but these were only put forth by him as suggestions of possibilities, not as ascertained facts."—Flower, P. Z. S., 1881, p. 162.

[2] To the above it may be added that Sea Elephants are not found in the high Antarctic latitudes, appearing not to reach the pack-ice and the shores of the Antarctic lands, the favorite haunts of the other southern Phocids.

ing appears to have been begun in 1803 on the coast of Patagonia, and was prosecuted there more or less regularly till 1819, during which period a total of about 15,000 barrels of sea-elephant oil appears to have been taken from Patagonia alone. In 1817 about 2,500 barrels were taken at the Falkland Islands, and also about 2,500 barrels in 1837. In 1820–'22 about 4,000 barrels were taken at the South Shetland Islands, and again about 2,000 barrels at the same islands in 1831. About 2,000 barrels are accredited to the South Georgian Islands in 1829. In 1838 5,000 barrels were obtained at Kerguelen Land; in 1838 and 1839 about 5,000 barrels were taken at the Crozet Islands. During the decade 1840–'50 nearly half the take of sea-elephant oil (about 16,000 barrels), came from Kerguelen Land, the total take, so far as statistics are available, being about 37,000 barrels. About this time the sea-elephant hunters began to visit Heard Island, and of the 84,000 barrels taken during the decade of 1850–'60, four-fifths were obtained at Kerguelen Land and Heard Island (the latter first discovered in 1853). During the following decade (1860–'70) about 36,000 barrels were reported as taken, nearly all of which came from the two last-named islands. The same is true of the decade from 1870 to 1880, but the amount of oil declined for this period to about 30,000 barrels, the decline being especially marked toward the close of the decade. It has been stated that during fifty years, beginning with the year 1837, not less than 175,000 barrels of sea-elephant oil were obtained from Kerguelen Land and Heard Island. As in later years, young of all ages as well as adults were taken, regardless, also, of season and condition, the number of sea-elephants annually destroyed at these seal islands must have been in the neighborhood 40,000 individuals, or a total of probably over 2,000,000.

"At these islands certain extensive beaches are described as being inaccessible from the water on account of the boisterous seas which constantly prevail, while precipitous cliffs render it impossible to transport the oil from these beaches to the vessels. Here great numbers of sea-elephants annually haul up in security to breed, thus preserving the species from extermination, which doubtless otherwise would long since have overtaken them.

"More or less sea-elephant oil has been taken annually since 1880, but the amount is small in comparison with the earlier years, owing to the increasing scarcity of the sea-elephants.

"The oil is chiefly used for softening wool, and for other purposes in the manufacture of cloth, for which it is especially adapted.

"The above relates only to the operations of Americans, and even for these the published statistics are far from complete (given principally by A. Howard Clark in Goode's 'Fishery Industries of the United States'). When we add to this the enormous number of sea-elephants that have fallen a prey to sealers of other nationalities, it is not a matter for surprise that these animals have long since been practically extinct, commercially speaking, except at the few points where the physical surroundings afford them protection from their inhuman enemies."[1]

Family *OTARIIDÆ*.

The Eared Seals are separable into two supergeneric groups, distinguishable externally by differences in the character of the pelage, in the length of the ears, in coloration, and in size. These groups, while rather sharply defined, especially as regards the nature of the pelage, are hardly entitled to rank as subfamilies. In the first of these the pelage is coarse and harsh, and without underfur; the ears are rather short, and the general coloration is yellowish brown in adults, darker and more reddish brown in the young, especially on the limbs, and the species all attain large size. This group includes the genera *Eumetopias*, *Otaria*, *Zalophus* and *Phocarctos*, each, except *Zalophus*, being monotypic. They are here mentioned in the order of size, the representatives of the first attaining the largest dimensions.

The second group includes the Fur Seals of commerce, in which the pelage consists of rather long overhair, beneath which is an abundant coat of very fine, soft, thick underfur, which gives to the peltries their high commercial value. The coloration in adults is grayish, the longer hairs being dark brown tipped with gray; in old individuals the coloration becomes decidedly gray, while the young in early life are black. The underfur is generally rich brown, lighter towards the base. This group includes the two genera *Callotaria* (= *Callorhinus* Gray) and *Arctocephalus*, the former embracing the Fur Seals of the North Pacific and the latter those of the southern seas; a species was also found formerly on the coast and islands of southern and Lower California, but it is now nearly extinct.

[1]Allen, in Proceedings of the Tribunal of the Fur Seal Arbitration, etc., Appendix to the United States Case, Vol. I, 1892, pp. 389, 390.

The following synopsis gives in brief the diagnostic characters and geographical distribution of the several genera.

SYNOPSIS OF THE GENERA.

A. Pelage harsh, without underfur; size large; color yellowish brown..... TRICHOPHOCACÆ.

a. Molars $\frac{6-6}{5-5} = \frac{12}{10}$; palate deeply concave.

b. Palatine bones prolonged nearly to the pterygoid hamuli, truncate posteriorly. Coasts and islands of southern South America..... *Otaria.*

b.' Palatine bones ending considerably in front of the pterygoid hamuli, narrowed and emarginate posteriorly. Aukland Islands..... *Phocarctos.*

a.' Molars $\frac{5-5}{5-5} = \frac{10}{10}$.

c. Palatine bones ending very far in front of the pterygoid hamuli, posterior border hollowed or emarginate; interorbital region moderately constricted; sagittal crest moderate. Molars $\frac{5-5}{5-5} = \frac{10}{10}$, a long diastema between $m^{\frac{4}{}}$ and $m^{\frac{5}{}}$. North Pacific. *Eumetopias.*

c.' Palatines much as in *Eumetopias;* interorbital region greatly constricted; sagittal crest enormously developed; molars $\frac{5-5}{5-5} = \frac{10}{10}$, no diastema between $m^{\frac{4}{}}$ and $m^{\frac{5}{}}$. California and Japan, and Australian Seas..... *Zalophus.*

B. Pelage soft, with abundant underfur; size much smaller; color gray, black in young. OULIPHOCACÆ.

a. Facial portion of skull broad, short, and high; brain-case short and broad; molar teeth small. North Pacific..... *Callotaria.*

a.' Facial portion of skull slender, narrow, elongated, and sloping; molars large. Southern Seas, mainly..... *Arctocephalus.*

From the foregoing it will be seen that the Eared Seals are geographically separated into two groups, the one northern, the other southern. The former includes the genera *Eumetopias*, *Zalophus*, and *Callotaria*; the latter *Otaria*, *Phocarctos*, and *Arctocephalus*. The last-named genus, however, furnishes a partial exception to this statement, for it not only ranges northward on the west coast of South America to the Galapagos Archipelago, situated on the equator, but has also a representative — or had, it being now practically extinct — as far north as the coast of Lower California, namely, the *Arctocephalus townsendi*, described by Merriam in 1897 from Guadalupe Island. As *Callotaria* formerly ranged southward in its winter migrations to the coast of California, it must have nearly or quite met the range of *Arctocephalus*. Fur Seals were actively hunted during the first third of the nineteenth century all along the Pacific coast of North America as far south as Lower California and the islands off the west coast of Mexico, in north latitude 18° to 20°. As, however, no specimens were secured for scientific examination, and the animals have

since become practically extinct, it is now impossible to determine the former southward limit of *Callotaria,* or the former northward limit of *Arctocephalus.*

While the Phocids, or Earless Seals, are circumpolar in distribution, in both hemispheres, the Eared Seals are confined, in the northern hemisphere, to the shores and islands of the Pacific Ocean, but are circumpolar in the southern hemisphere. It is noteworthy, however, that in neither hemisphere do they reach nearly so high latitudes, and never range into the pack-ice, as do most of the species of the Phocidæ, in both the Arctic and Antarctic regions.

Genus OTARIA Péron.

Otarie Péron, Ann. du Mus. d'Hist. Nat., XV, 1810, 300. The only species mentioned is Steller's Sea Lion, but he gives a reference to his "Voyage aux Terres Australes," correctly citing volume and page as "t. II, p. 37."

Otaria Péron, Voy. aux Terr. Austr., II, 1816, 37, footnote and *passim,* pp. 40–52, in part. Type, by elimination, *Phoca byronia* Blainville = *Otaria leonina* Péron, 1816, et auct. = *Phoca leonina* Molina, 1782, preoccupied by *Phoca leonina* Linn., 1758.

Otoes G. Fischer, Mém. Soc. Imp. des Sci. Nat. de Moscou, V, 1817, 445. = *Otaria* Péron, 1816.

Otaria Gray, Zoöl. Erebus and Terror, Mamm., 1844, 5, in part.

Otaria Gill, ex Péron, Proc. Essex Inst., V, 1866, 7.

Otaria Peters, Monatsb., k. p. Akad. Wissen. Berlin, 1877, 505. "*Otaria* Péron, s. s."

Platyrhyncus F. Cuvier, Dict. des Sci. Nat., XXXIX, 1826, 555 = Le Platyrhinque, F. Cuvier, Mém. du Mus., XI, 1824, pl. xv, fig. 2 (skull), in part. Type, as determined by the figured skull, *Otaria leonina* auct.

Generic Characters. — Palatine bones extending nearly to the pterygoid processes, deeply concave, truncate posteriorly. Molars in a continuous series, $\frac{6-6}{5-5} = \frac{12}{10}$. Ears short. Pelage without underfur.

General History. — The genus *Otaria* contains but a single well-established species, the *O. byronia* (= *O. leonina* or *O. jubata* of most authors) of southern South America. Various other species have been

proposed, but they rest thus far on very unsatisfactory evidence, as will be noted later.

All the Seals were placed by all authors in the Linnæan genus *Phoca* till Péron, in 1810,[1] proposed to consider the Eared Seals as a new genus, "sous le nom d'*Otarie*." In 1816 he introduced, informally, the generic name *Otaria* for these animals, which he employed incidentally and consistently for them throughout his chapter on the Sea Elephant in the second volume of the "History" of Freycinet's "Voyage aux Terres Australes."[2] He mentioned here, in footnotes and in the text, three species of Eared Seals, and subsequently two others in the same volume, as follows: (1) *Otaria ursina* (pp. 39, 41, 42, 49, 52) = *Phoca ursina* Linn., based on the Sea Bear of Steller; (2) *Otaria leonina* (pp. 40, 65, etc.) = Sea Lion of Forster; (3) *Otaria jubata* (p. 40, footnote) = *Leo marinus* of Steller; (4) *Otaria cinerea* (p. 77), Iles Decrès, — not identifiable; (5) *Otaria albicollis* (p. 118), Isle Eugène. The first three of these names (*O. ursina*, *O. leonina* and *O. jubata*) are perfectly identifiable with previously described and now well-known species. The other two (*O. cinerea* and *O. albicollis*) were given to supposed new species, but so inadequately described as not to be satisfactorily identifiable.[3]

Up to this time all of the Sea Lions had been regarded as forming a single species, named *Phoca jubata* by Schreber in 1776, and all the Sea Bears, or Fur Seals, as referable to the *Phoca ursina* of Linnæus (1758). Péron thus for the first time not only separated the Otaries from the Phocids, but he also distinctly separated the Northern Sea Lion from the Southern Sea Lion, retaining for the former (very properly, as will be

[1] Ann. du Mus. d'Hist. Nat., Vol. XV, 1810, p. 300, footnote. He here cites his use of the name "Otarie" (probably written by him *Otaria*) in "Voyage aux Terres Australes, t. ii, p. 37," which work was not issued until long after the sheets were printed, owing to delay with the plates. *Otaria* Péron is generally cited from the "Voyage," 1816, which appears to be its proper date.

[2] Voyage de découvertes aux Terres Australes, Historique, Tome Second, 1816 . . . Chapitre XXIII, "Histoire de l'Élephant marin, ou Phoque à trompe [*Phoca proboscidea*, N]: Pêches des Anglois aux Terres Australes," pp. 32–66, pl. xxiii.

[3] Mr. G. W. Clark, who some years ago made them the subject of special investigation (see his valuable paper "On the Eared Seals of the Islands of St. Paul and Amsterdam, with Description of the Fur Seal of New Zealand, and an attempt to distinguish and rearrange the New Zealand Otariidæ," in P. Z. S., 1875, pp. 650–677, pll. lxx–lxxii, and 8 text cuts), considers *O. cinerea* as closely related to *Arctocephalus forsteri*, but possibly entitled to recognition as a species, without, it seems to me, very good grounds. He considers *O. albicollis* as identical with Gray's *Arctocephalus lobatus*, which is perhaps probable, though not satisfactorily provable.

shown later) the specific name *jubata*, and giving a new name to the latter, which unfortunately proves to be untenable.[1]

In 1817 G. Fischer, evidently ignorant that Péron had established the generic name *Otaria* for the Eared Seals, proposed for them the name *Otoes*,[2] basing his name entirely on G. Cuvier's "Les Phoques à oreilles extérieures," in the "Règne Animal" (I, 1817, p. 166), his own account of which is an unabridged paraphrase of Cuvier's, even to Cuvier's error in respect to the incisors. He cites as referable to it "*Phoca jubata*, *ursina*, Lin. Gmel.," in other words, the Sea Lions (*Phoca jubata* auct.) and the Sea Bears (*Phoca ursina* auct.) as they were known to Cuvier and naturalists generally at the time, who believed there were only one species of each, both common to the Arctic and Antarctic regions. No one but Péron appears to have thought otherwise for the next ten years; even as late as 1823, G. Cuvier spoke[3] derisively of Péron's assumption that none of the seals of the "hemisphère antarctique" were "de même espèce que ceux du nord."

It consequently happens that the genus *Otoes* Fischer, 1817, is an exact synonym of *Otaria* Péron, 1816. It is therefore inadmissable to assume, as has been recently done,[4] that the name *Otoes* is available for the northern Fur Seals, on the ground that what Fischer did "was simply to apply a generic name to Cuvier's group [= "Otaries Péron"] whose name Cuvier avowedly took, which . . . . was based chiefly on the northern and not the southern fur seal.". While the first part of this statement is perfectly correct, the latter is not, Cuvier's *Phoca ursina* including a southern Fur Seal ("*Phoca pusilla*") and a southern Sea Lion ("le phoque jaune de Shaw, etc.,"), as well as a citation of "Buff., Supp. VII [lege VI], pl. xlvii," which plate Buffon states is after a design from nature by Forster, which, as all investigators of the group know, relates to the Fur Seal of

[1] The following quotations from Péron show the manner in which the two names *Otaria leonina* and *Otaria jubata* were introduced. Péron (*l. c.*, p. 40, in the text) says: ". . . (Forster, 2e Voy. de Cook, tom VIII, pag. 56). L'auteur parle ici de l'Otaria Leonina, N.a"; and adds in a footnote to the same page:

"a Quelque singulier que puisse être le phénomène dont il s'agit, il n'est pas cependant particulier aux grands Phocacés des régions Australes, STELLER a observé quelque chose d'analogue sur le Lion marin du Nord [Otaria jubata, N.]" — and then follows a quotation from Steller.

New Zealand, Forster's drawing having been made at Dusky Bay, on the southeastern coast of South Island, New Zealand, March 31, 1773.[1]

In 1824 F. Cuvier[2] separated the Otaries (which he still looked upon as consisting of only two species) into two groups, under vernacular French names, as follows: (1) "Arctocéphale," and (2) "Platyrhinque." He says "nous prenons le type de ce genre Arctocéphale dans l'Ours marin, *Phoca ursina*." Of the second he says: "Le lion marin (*Phoca leonina*) paroît être le type de ce dernier genre, auquel nous donnerons la dénomination de Platyrhinque."

Two years later he introduced these terms in proper Latin form, as, respectively, *Arctocephalus* and *Platyrhyncus*[3] and says, "quoique l'un et l'autre de ces genre ne se composent encore manifestement que d'une seule espèce." One he calls "*Arctocephalus ursinus; Ursus marinus*, Steller, Novi comment. petrop., 11, p. 331"; vaguely referring also to Pernetty and Forster. The other he calls "*Platyrhyncus leoninus;* Lion marin, Steller, Nov. act. petrop., 2; Forster, 2 Voyages de Cook, t. 4; Pernetti, Voyage aux îles Malouines, t. 2, pl. 10," etc. No specimens are definitely mentioned in either of Cuvier's articles, but a skull of each genus is figured in his first paper. These illustrations are based not on Steller's animals mentioned in the text, but, in the case of *Platyrhyncus*, on the Southern Sea Lion, and in the case of *Arctocephalus* on a fur seal from the Cape of Good Hope. Cuvier's plate xv (*l. c.*) therefore determines the type for both groups, which in the case of *Arctocephalus* is the Cape of Good Hope species, *Arctocephalus antarcticus* (Thunberg), and in the case of *Platyrhyncus*, the sea lion of Patagonia and the Falkland Islands, named *Otaria leonina* by Péron. This would restrict *Otaria* to Steller's Sea Lion were it not, fortunately for the present current nomenclature of the group, that the name *Platyrhynchus* is doubly preoccupied — for a genus of birds by Desmarest in 1805, and by Thunberg in 1815 for a genus of Coleoptera.

It hence fortunately happens that the first valid restriction of *Otaria*, after the Fur Seals (*Arctocephalus*) were removed, was made in 1866, when Gill established *Eumetopias* for the sea lion of Steller, and *Zalophus* for

Otaria rufa Philippi, An. Mus. nac. Chile, I., Zool., 1892, 6, 28, pl. xiii, fig. I, animal. Length, 990 mm.

External Characters.[1] — General color of adult light yellowish brown, lighter on the head, darker and more reddish brown on the buttocks and limbs; muzzle and naked membranes of the feet black. Young dark chocolate brown, much darker than the adult, the coloration becoming gradually lighter with age. Females are said to be like the males in coloration.

Length of adult male from muzzle to end of tail about 6 to 7 feet, and from the muzzle to the end of the hind flippers about 8 to 9 feet. Female about one third less in linear measurements.

The old males are described by the early voyagers as maned like a lion, but this is in no strict sense true. The hair is longer on the neck and shoulders than elsewhere, but the maned effect is due mainly to the thick skin being thrown into heavy folds when the head is raised.

Skull. — The skull of this species has been so often figured and is

[1] The material collected by the Princeton Patagonian Expeditions relating to the Pinnipedia not having been conveniently accessible during the preparation of this work I have drawn upon previously published descriptions in dealing with their external and osteological characters. Through the kindness of the authorities of the United States National Museum and the Cambridge Museum of Comparative Zoölogy I have had opportunity to restudy a considerable series of skulls of both the Southern Sea Lion and the Southern Sea Bears, and have utilized to some extent material from my "Monograph of the North American Pinnipeds," published in 1880. I am also indebted to the kindness of Prof. W. B. Scott for Plate XXI, illustrating the skeleton of *Otaria bryonia*, based on a mounted specimen from Patagonia, collected by the Princeton Patagonian Expeditions.

now so well known that a detailed description is unnecessary. It varies greatly in the two sexes, the male skull being much larger than that of the female, with an excessive development of the processes and crests, as age advances. The average dimensions of old male skulls from the Straits of Magellan are: Total length 350 mm., ranging in a series of 8 old skulls from 325 to 372; zygomatic breadth 223, ranging from 210 to 237. Four old female skulls give an average total length of 260 (252 to 277), and a zygomatic breadth of 143 (140 to 146).[1]

Dr. James Murie[2] and Dr. William Turner[3] have made known the anatomy of this species in great detail, their work being based on Falkland Island specimens.

The Southern Sea Lion bears a strong general similarity externally to the Northern Sea Lion, which it resembles in color and proportions, but, judging from the skulls, it is about one eighth smaller. In cranial characters the two animals are remarkably distinct for members of the same family, not only in dental formula but in the formation of the bony palate. But they appear to agree as closely in habits as in external appearance, both being polygamous, and resorting to particular islands or coasts at a definite season of the year to bring forth their young.

GEOGRAPHICAL DISTRIBUTION.—The Sea Lions of the coasts and islands of southern South America are commonly believed to be referable to a single species, of rather wide distribution. It formerly occurred in great abundance at the Galapagos Islands, and is still found there in small numbers[4]; also along the coasts of Peru and Chili to Cape Horn, resorting especially to some of the islands of this part of the South American coast. It also frequented the eastern coast of Patagonia, and still ranges north to Lobos Island, off the mouth of the Rio de la Plata, and formerly north to the coast of Brazil, off Sta. Catharina[5]. It was formerly numer-

ous at the Falkland Islands and in the Tierra del Fuego Archipelago. It does not appear to have been reported from the South Shetland and South Georgian Islands, nor from any point more remote from the South American coast than the Juan Fernandez and Falkland Islands. In the report on the *Southern Cross* Collections (1902), it is not mentioned as having been met with by the naturalists of this expedition during their long cruise in Antarctic waters.

Respecting their recent occurrence on the eastern coast of Patagonia Mr. Barnum Brown (MSS. notes) says: "Two herds of sea lions were found on the coast of Patagonia at a point about twenty miles south of the mouth of the Santa Cruz River, where they have bred and been noted since the earliest settlements along the southern coast. They occupy two distinct rookeries, although not more than half a mile apart; the herd furthest north, numbering less than 200 head, lives in tide-worn crevices and caverns, from which they slide into the sea with great noise when disturbed. The southern and largest herd has over 300 head, which lives, when ashore, on the open shingle beach under the cliffs. Others were seen off Cape Hall, but they were not in rookeries."

Nomenclature and Technical History.—The early voyagers to high southern latitudes met with Sea Lions, Sea Bears, and Sea Wolves at various points on or near the coast of southern South America and described them in narrations of their voyages, usually in vague terms, but sometimes with sufficient detail to render them recognizable, when the locality is considered, in the light of our present knowledge of the subject. The technical history of the present species may be said to have begun with Pernetty,[1] whose Lion marin, though poorly described and badly figured, observed by him at the Falkland Islands in 1764, is identifiable as this animal, although his account of it is more or less confused with that of the Sea Lion of Anson. Pernetty's Lion marin became, in 1776, in part the basis of Schreber's *Phoca jubata* (*l. c.*), who quotes Pernetty as authority for his statement that the male has long curly hair ("langen krausen Haare") on the nape and neck, like the male lion, and a length of 25 feet and a girth of 19 to 20 feet,[2] and for its occurrence at the Falk-

[1] Voyage aux Iles Malouines, 1769, p. 447, pl. viii, fig. 1.

[2] It is hard to say whether Pernetty meant this statement to apply to his Lion marin or to Lord Anson's Sea-lion, which Pernetty insists was injudiciously applied to what he calls Loup-marin, his statements are so confused.

land Islands. Schreber also mixes Pernetty's account of its habits with Steller's, although Steller is necessarily his main authority, Pernetty's information is so meagre. As, however, Steller gave no figure of the sea lion, Schreber supplied this deficiency by copying Pernetty's grotesque caricature of the Falkland Island animal. Schreber's *Phoca jubata* was thus composite, though based primarily on Steller.

For the next fifty years, or till 1828, nearly all systematic writers followed Schreber in considering the northern and southern sea lions as specifically identical. Péron, in 1816,[1] was the first author who had the hardihood to assert that they were specifically distinct, and acting upon this belief he bestowed the name *leonina* upon the southern one and restricted the name *jubata*, very properly, to the northern one, calling them respectively *Otaria leonina* and *Otaria jubata*, without, however, pointing out their distinctive differences. This he doubtless did, or intended to do, in a paper on the Pinnipedia he left in manuscript at his death, in 1810, which was never published. Thus Péron, as the "first reviser," fixed the name *jubata*, as he had a right to do, very appropriately on the *Leo marinus* of Steller.

Unfortunately his name *leonina* for the Falkland Islands species proves untenable, although subsequently employed for it for many years by numerous authors. Its untenability in this connection is due to the fact that Molina, in 1782, gave the name *Phoca leonina* to the same species, as represented on the coast of Chili, notwithstanding the fact that he knew that Linnæus had previously (1758) bestowed the same name (*Phoca leonina*) upon the Sea Elephant (now *Mirounga leonina* auct.).

A large number of specific names have been based, since 1782, on the sea lions of the coasts and islands of southern South America, and from these it is necessary to replace the name *leonina* of Molina and Péron. The first of these, in order of time, is (1) *Phoca flavescens*, given by Shaw in 1800, and founded on the eared seal of Pennant. Pennant's description was based on a young otary in the Leverian Museum, only about two feet in length, said to have come from the Straits of Magellan. It is entirely indeterminable from the description, but the locality, if correctly indicated, leads to the inference that it was more likely a young sea lion than a fur seal; and this being the case, it may be hypothetically referred to the genus *Otaria*, to which it has been provisionally assigned by the

[1] Voy. aux Terr. Austr., II, 1816, pp. 37–40, *passim*.

majority of writers for the last fifty years; but Gray, in 1871, referred it to *Phocarctos hookeri*.[1] The name *flavescens* evidently rests on a basis too unsatisfactory to warrant its use for any species.

In 1820 Blainville[2] described and figured the skull of a sea lion found by him in the Hunterian Museum of London, bearing the legend "Sea Lion from the island of Tinian, by Commodore Byron." His description of this skull is given in considerable detail, and his figure, though rough, aids in determining beyond doubt its reference to the sea lion (*Otaria*) of southern South America. On a later page he bestowed upon it the name *Phoca byronia*. This skull, fortunately, was afterward deposited in the British Museum, and finally transferred to the osteological collection of the Museum of the Royal College of Surgeons, where it is still preserved. It has been examined by numerous competent authorities, as G. Cuvier, Nilsson, Gray, Peters, Burmeister and Flower, who have uniformly referred it to *Otaria jubata* auct. Gray says (Suppl. Cat. Seals and Whales, 1871, p. 13): "I cannot see any difference between the skull in the College of Surgeons, on which *Phoca Byronia* was founded and those [of *Otaria jubata*] in the British Museum." Flower, in his Catalogue of the Osteological Collections of the Museum of the Royal College of Surgeons, enters this skull with the following comment: "This specimen was brought to England in 1769, by Commodore Byron, as is stated, from Tinian, one of the Ladrone Islands, and was for many years preserved in the British Museum. It is not improbable that there has been a mistake as to the locality assigned to it, or that it was brought to the island by some human agency or accident, as living Sea-Lions of this species have never been met with nearer Tinian than the Galapagos Islands. There is no mention of it in Byron's published narrative. De Blainville has given a very incorrect description and figure of this specimen in the 'Journal de Physique,' tome xci., pp. 287 and 300 (1820), under the name of *Phoca byronia*, whence *Phoca byronii*, Desmarest, Mammalogie, p. 240 (1820)."—Flower, *l. c.*, II, p. 189.

As stated by Flower, the skull could not, therefore, as alleged, have come from the Island of Tinian, one of the Mariana or Ladrone Islands (lat. 15° N.), which are situated far outside of the range of any known

[1] Suppl. Cat. Seals and Whales, 1871, p. 14.

[2] Journ. de Phys., XCI, Oct., 1820, p. 287, fig. 3 of plate dated Dec., 1820; named *Phoca byronia* on p. 300.

Pinniped. The essential facts of the case, then, are: (1) The skull on which the name *Phoca byronia* was based is beyond doubt a skull of the sea lion (*Otaria jubata* auct.) found on the islands and coasts of southern South America; (2) that it is also the first name exclusively based on that animal that is perfectly identifiable and not preoccupied. It is hence necessarily the only available name for this species, which must stand as **Otaria byronia** (Blainville).[1]

Several subsequent names also relate exclusively to this species, which of course become synonyms of *Otaria byronia*. Among these may be mentioned *Otaria molossina* Lesson & Garnot, 1826, based on the Sea Lion of the Falkland Islands, very fully described and well figured in the Zoölogy of the Voyage of the *Coquille*, from a semi-adult male specimen. Other synonyms were added the following year (1827) by Lesson, as *Otaria pernettyi*, based on Pernetty's account of the Falkland Island Sea Lion, and *Platyrhyncus uraniæ*, based on the "Otarie Guérin" of Quoy and Gaimard, — a young or female sea lion, also from the Falkland Islands. In 1841 Müller added *Otaria platyrhinchus*, based on the type of F. Cuvier's genus *Platyrhyncus*, and *Otaria chilensis*, based on specimens obtained by Philippi on the coast of Chili. In 1844 von Tschudi added *Otaria ulloæ* = the female of *Otaria byronia* (= *jubata* auct.) as recognized by Peters, Gray, and Burmeister. Peters in 1866 added *Otaria godeffroyi*, from the Chincha Islands, off the coast of Peru, which he later considered doubtfully distinct from *O. jubata*, and to which it was subsequently referred by Gray and Burmeister as representing the male of that species. Gray, in 1871, described an *Otaria minor* and an *Otaria pygmæa*, both based on skulls from unknown localities, and previously referred by him to *O. jubata*. Finally, Philippi, in 1892, added three more, namely, *Otaria velutina*, *O. fulva* and *O. rufa*, besides reviving *O. molossina* and *O. chilensis* of previous authors, making six species recognized by him from the coast and islands of Chili. His descriptions and figures of most of them are based on very young specimens, some of them still retaining part of the milk dentition.

[1] Desmarest, the same year (Mamm., I, 1820, p. 240), gave a description of the same skull, under the name *Phoca byronii*, "espèce nouvelle, fondée par M. de Blainville," etc., his account having been evidently based on Blainville's manuscript description. He believed it to be allied to the Sea Elephant, as did Lesson in 1827. Evidently Desmarest's account was written before Blainville's description was published, and in the uncertainty as to which account was actually first published, it is best to consider Blainville as the author of the species and accept his form of the name.

Note on the Name of the Northern Sea Lion.

As already said, *Phoca jubata* Schreber was based primarily on the *Leo marinus* of Steller, the description being almost wholly from Steller, with references to the Sea Lion of Pernetty; and as Steller did not figure the Sea Lion, as he did the Sea Bear, Schreber copied Pernetty's execrable figure of the Sea Lion of the Falkland Islands, supposing, as did subsequent naturalists generally for the next fifty years, that the Northern and Southern Sea Lions were specifically the same. In 1816, as stated above, Péron asserted their specific distinctness, restricted the name *jubata* to the Northern Sea Lion, and gave what he evidently supposed to be a new name, *leonina*, to the Southern Sea Lion, and transferred both from *Phoca* to his new genus *Otaria*. As already explained, the name *Otaria leonina* is untenable on account of Molina's having previously called the same animal *Phoca leonina*, a name preoccupied by Linnæus's *Phoca leonina* for the Sea Elephant.

Lesson in 1862 renamed the Northern Sea Lion *Otaria stelleri*, and the name *stelleri* has since been in almost universal use for this animal. In view of Péron's restriction, twelve years before, of the name *jubata* to this species, the name *stelleri* obviously becomes a synonym of *jubata*, and the correct name of Steller's Sea Lion is **Eumetopias jubata** (Schreber). Unfortunate as it may seem, the history of the case shows the necessity of the change, under the current rules of nomenclature.

Early History of the Northern and Southern Sea Lions.

The case of the Northern and Southern Sea Lions, often known respectively as Steller's Sea Lion and Forster's Sea Lion, furnishes an instructive illustration of the struggles of zoölogists in arriving at a fair knowledge of animals long known only from the vague accounts of explorers and travellers, who, while perhaps eminent in other ways, were not good naturalists. The case of the Fur Seals, or Sea Bears, of the northern and southern hemispheres is equally complicated and interesting, but need not be dealt with at length in this connection; it may suffice to say that the history of these groups is perfectly parallel to that of the Sea Lions. Our knowledge of the northern forms dates, in both cases, from Steller (1751), whose classic memoir on these animals forms a conspicuous landmark in the early history of mammalogy. In his "De Bestiis Marinis" both

the Sea Lions and the Sea Bears were made known with admirable detail and clearness, and for nearly a century this memoir remained our chief source of information respecting them.

It was, however, quite different with the large Pinnipeds of the southern hemisphere, including the Sea Elephant as well as the Sea Lions and the Sea Bears. They were first made known by the early voyagers to the Southern Seas, as Dampier (1697), Freizer (1717), Anson (1748), Byron (1769), Pernetty (1770), Forster (1777), Cook (1784), Weddell (1825), and others, who gave, however, only very imperfect and erroneous accounts of them; and yet they were taken by systematists many years later as the basis of supposed species, notably by Desmarest (1817 and 1820) and Lesson (1828). Thus each of the South American species was named over and over again by compilers who apparently, in most instances, had never seen a specimen of any of them. The early voyagers appear to have taken home very few specimens, and these were not always correctly labelled as to locality of capture. Thus, as in the case of the Commodore Byron skull, already mentioned, they were sometimes attributed to localities remote from the home of any species of Pinniped, and in other cases it was uncertain whether the specimen came from the vicinity of Cape Horn, or the Cape of Good Hope, or the Australian seas, the locality being finally given as the "Antarctic Seas," or as "unknown." In some cases the specimen consisted of a skin without a skull, sometimes of a very young animal, as in the case of Pennant's Eared Seal and Buffon's Petit Phoque; in other cases of a skull without the skin, sometimes adult, sometimes young. While these animals were being slaughtered on their breeding grounds by sealers, for their skins or oil, by the tens of thousands annually during the latter part of the eighteenth and early part of the nineteenth centuries, and their habits and haunts had become well known, scarcely a specimen reached any of the scientific museums of Europe, or fell under the observation of competent naturalists. It was not apparently till about 1840 that any mammalogist had had specimens of the northern and southern sea lions for comparison, when Müller found skulls of both in the Berlin Museum, and was able to confirm for the first time their specific distinctions by actual comparison of their skulls. In the Paris and London Museums there were a few skulls of the southern species, but none of the northern, until about 1859, when a skull of this animal reached the British Museum, received from California, and was

described by Gray as a new species. Neither had he up to that time seen a skull of the northern fur seal.[1]

Till many years after the middle of the nineteenth century no one had opportunity to recognize the great differences due to age and sex that obtain in these animals; and it was therefore not strange that when, some years later, isolated skulls from different localities and of different ages began to arrive at the British, Berlin, and other Museums, they should be taken as the basis of supposed distinct species, with the result of adding to the long array of synonyms that now cumber the literature of the subject. It was not till about 1870 that sufficient material for determining the cranial differences due to age and sex began to accumulate, when good series of skulls and skeletons, as well as of skins, of the northern sea lions and fur seals reached the Museum of Comparative Zoölogy at Cambridge, and the National Museum in Washington, and also of the southern forms as represented at the Galapagos Islands.

Finally, as I stated in 1880:[2] "Of about fifty synonyms pertaining to the Eared Seals, probably two thirds have been based, directly or indirectly, upon differences dependent on sex and age, and the rest upon the defective descriptions of these animals by travellers."

FIGURES. — The Southern Sea Lion has been figured repeatedly, both as regards the skull and the animal. The early figures are naturally crude and of little value; the later ones meet all requirements of detail and accuracy. In the following enumeration the principal illustrations of the animal and its external features are first mentioned, and then those of the skull and its general anatomy.

Animal. — The first published figure of this species is probably that given by Pernetty,[3] in 1769, based on the sea lion of the Falkland Islands. This, though a wretched caricature, was copied by Schreber to illustrate his *Phoca jubata*, and this fact constitutes the chief interest and importance of Pernetty's figure.

[1] Dr. Gray, in 1864 (P. Z. S., 1864, p. 34) said: "I am not aware that the *Leo marinus* of Steller exists in any Museum." In 1868, he wrote as follows: "When I published my 'Catalogue of the Seals in the British Museum,' in 1850, I was satisfied from Steller's description that the species he described from the Arctic regions were distinct from those found in the southern seas; and when I at last succeeded in obtaining specimens and skulls from the northern regions of the Pacific, I not only found that my idea was confirmed, but that they did not belong to the same genera." — Ann. and Mag. Nat. Hist. (4), I, Feb., 1868, p. 99.

[2] Hist. N. Am. Pinnipeds, 1880, p. 227, footnote.

[3] Voy. aux les Iles Malouines, II, 1769, pl. viii, fig. 1.

In 1782 a fairly good representation was published by Buffon[1] from a drawing made by Forster, also at the Falkland Islands. The species was again illustrated by Lesson and Garnot in 1826,[2] who gave a colored figure of a young animal from the Falkland Islands, under the name *Otaria molossina*. This figure was copied by Hamilton in his "Carnivorous Amphibia." Hamilton gave also in 1839 a poor figure of what he called "The Sea-Lion of Pernetty,"[3] based on a specimen in the Royal Museum of Edinburgh, which, he says, "was brought from the antarctic regions some years ago."

Tschudi in 1844–46,[4] gave a figure of his *Otaria ulloæ*, from a young example about four feet long, from the coast of Peru.

The next figure appears to have been published by Sclater,[5] an excellent representation of a young male in the Garden of the Zoölogical Society of London, "captured on the sea shore near Cape Horn." Other figures from life of the same specimen, according to Gray and Murie, were published in "Land and Water," "The Illustrated London News," and "The Boys' Own Magazine" (VI, No. 33, p. 214). The cut from "Land and Water" was republished by Dr. Murie in his memoir on the Anatomy of *Otaria jubata*,[6] and duly acknowledged. He also gave other text cuts illustrating (fig. 2, *l. c.*, p. 539) its manner of swallowing food; a group (fig. 3, *l. c.*, p. 556) of Sea Lions in a variety of positions on land and in the water, from drawings made from the living animal in the Zoölogical Society's Gardens; and also additional attitudes (fig. 4, *l. c.*, p. 575) assumed, drawn from life. In the plates accompanying Dr. Murie's admirable memoir are given figures of the fore and hind flippers, and of the hinder portion of the body, showing the external genital organs, the ear, eye, muzzle and throat, and the skin ridges on the breast (*l. c.*, VII, pll. lxvii, lxviii and lxix). Beddard, in his memoir "On the Structure of Hooker's Sea Lion" (*Arctocephalus hookeri*),[7] gave a side view of the head, and a front view of the muzzle of *Otaria "jubata,"* in comparison with views of similar parts in *Arctocephalus antarcticus* and *Zalophus californianus*. These figures are of special interest as showing the short ears and the

character of the nose-pad in *Otaria* as compared with those parts in *Phocarctos* and *Arctocephalus*.

The pictorial history of this animal, as regards its external characters, was further supplemented by Philippi, in 1892, by a series of very inartistic and unimportant figures, based in large part on immature examples from Chili.

Skull and General Anatomy.—The earliest figure of the skull, and one of special importance from a nomenclatural standpoint, was published by Blainville in 1820,[1] since on this skull is based the name *Phoca byronia;* this figure, though rather unsatisfactory, is readily identifiable as that of *O. jubata* auct., as is shown further by his description of it. In addition to this, the skull is still (or was recently) in the Museum of the College of Surgeons of London, and, as already stated (*antea*, p. 112), has been repeatedly examined and identified by competent authorities as belonging to this species. In fig. 4 of the same plate Blainville figures the dentition (side view) of another skull of this species under the name of "Sea lion from islands Falckland." The first skull was erroneously supposed to have come from the Island of Tinian, one of the Mariana group.

The next figure of a skull that seems identifiable with the Southern Sea Lion is that given by G. Cuvier in 1823 in his "Ossemens fossiles,"[2] a side view of a "tête adult du Cap" (*l. c.*, p. 222), which appears to be the same skull as that figured by F. Cuvier in 1824,[3] the side view given by F. Cuvier corresponding with the figure given by G. Cuvier. F. Cuvier's figures *e* and *f* of this skull, particularly fig. 2, *f*, of the ventral surface, leave no doubt of its reference to the southern sea lion. This author, however, does not state the locality or history of either of the skulls figured by him as the types respectively of his "Platyrynque" and "Arctocéphale." As said above, and also earlier in this paper (*antea*, p. 104), there is no doubt of the identity of his type skull of the Platyrhinque with the *Otaria jubata* of modern authors.

Hamilton, in 1839, in the volume of Jardine's "Naturalist's Library" devoted to the "Amphibious Carnivora," gave a rude side view of a skull he attributed to the "Sea-lion of Steller" (p. 232), but which is unques-

[1] Journ. de Phys., XCI, 1820, pl. (with the number for December, 1820), fig. 3.

tionably, as is his description of the skull, referable to the southern sea lion. The history of the specimen is not given, and the figure has no special value.

In 1840 Blainville figured the skeleton, and also the skull and dentition[1] of a very old male, four views, one third natural size, being given of the skull. The skeleton, it is stated, came from the coast of Chili, as did also the skull, the latter having been obtained by Dr. Néboux on the cruise of the *Vénus*.

In 1844, in the Zoölogy of the *Erebus* and *Terror*,[2] Gray gave two views, profile and from below, of the skull of a young specimen. This is presumably the same skull figured by him ten years later in his "Catalogue of Seals in the British Museum" (p. 46), apparently from the "west coast of South America" (*cf. l. c.*, p. 48), under the name *Otaria leonina*, and again republished in his "Catalogue of Seals and Whales" (1866, p. 58).

In 1866 Peters gave three views of the skull of *Otaria godeffroyi*[3] and also three of a skull of *Otaria ulloæ* Tschudi,[4] both of which species he later referred to *O. jubata* auct.

In 1872–1874 Dr. Murie, in his well-known memoir (*l. c.*) on the "Anatomy of the Sea Lion (*Otaria jubata*)," published an admirable series of illustrations of not only the skull but of the general anatomy, including the soft parts as well as the skeleton. Two wood cuts in the text[5] (VIII, p. 506) give comparative views of the palatal surface of the skull of the male and female, and plates lxxv and lxxvi a series of figures of the skull of a young male, including sectional views. Plate lxxvii illustrates the skeleton and numerous separate bones, and a series of skulls of different ages, from a fortnight old to old adults, in profile and from above, showing "progressive growth." Five additional plates[6] are devoted to the myology, and five others[7] to the brain, sensory, vascular, digestive, urinary, and genital organs.

In 1883, Burmeister, in the Atlas (livr. 2, pl. viii, 17 figures) to his

[7] *Op. cit.*, VIII, pll. lxxviii–lxxxii.

"Description Physique de la République Argentine," gave a series of figures of skulls of old and young of both sexes, showing individual and sexual variation, and also variation due to age. This is a most important series of figures, based on specimens from the Lobos Islands, off the mouth of the Rio de la Plata.

In 1892 Philippi figured a number of skulls, including those of three supposed new species, all, however, based on very young animals, several of the skulls showing part of the milk dentition, besides other features of immaturity.

Otaria byronia has thus been very fully and satisfactorily illustrated as regards both its external characters and internal structure.

Genus ARCTOCEPHALUS F. Cuvier.

Arctocéphale, F. Cuvier, Mém. du. Mus. d'Hist. Nat., XI, 1824, 205, pl. xv, fig. 1, *a*, *b*, *c*.

Arctocephalus F. Cuvier, Dict. des Sci. Nat., XXXIX, 1826, 554. Same as above. Type, "*Phoca ursina*" = *Phoca antarctica* Thunberg.

Halarctus Gill, Proc. Essex Inst., V, 1866, 7, 11. Type, *Arctocephalus delalandi* Gray = *Phoca antarctica* Thunberg.

Arctophoca Peters, Monatsb. Akad. Berlin, May, 1866, 276 (subgenus of *Otaria*). Type, *Otaria* [*Arctophoca*] *philippii*, sp. nov.

Euotaria Gray, Ann. & Mag. Nat. Hist. (4), IV, Oct., 1869, 269 ("South America"); Suppl. Cat. Seals and Whales, 1871, 20. Type and only species, *Arctocephalus nigrescens* Gray = *Phoca falklandica* Shaw.

Gysophoca Gray, Ann. & Mag. Nat. Hist. (4), IV, Oct., 1869, 269 ("Australia"); Suppl. Cat. Seals and Whales, 1871, 24. First species, *Otaria* (*Arctocephalus*) *cinerea* Peters = *? Otaria cinerea* Péron, 1816 = *Otaria cinerea* Quoy & Gaim., 1830 = *Otaria forsteri* Lesson, 1828.

The only species referred by F. Cuvier (*l. c.*, 1826) to his genus *Arctocephalus* is his "*Arctocephalus ursinus; Ursus marinus*, Steller, Novi comment. petrop., 11, p. 331," which he elsewhere mentions as "*Phoca ursina*, Linn.," and distinctly says is the type of his genus *Arctocephalus*.[1] On this account many subsequent writers have given the type of *Arctocephalus* as *Phoca ursina*. Under this name, however, Cuvier associated not only Steller's Sea Bear, but the Fur Seal observed by Per-

[1] Mém. du Mus., XI, 1824, p. 208; Dict. des Sci. Nat., XXXIX, 1826, p. 553.

netty at the Falkland Islands, and the Fur Seal of the Cape of Good Hope, (*l. c.*, 1826, p. 554), — in other words, all the fur seals then known. As F. Cuvier figured the type skull of his genus *Arctocephalus*, his figure must determine the type of the genus. Furthermore, it is a well-known fact that no skull of Steller's *Ursus marinus* reached any European museum till many years after Cuvier established his genus *Arctocephalus;* it was thus impossible that this species should have served as the basis of his figure and description of the skull. Besides, his figure does not leave the least doubt as to its being, not this species, but some one of the several southern species of fur seal. Cuvier, himself, does not intimate in either of his two accounts of the genus *Arctocephalus* the source of his specimen. In another work,[1] of about the same date, he describes the dentition of certain of the seals, and says: "J'ai tiré cette description de une tête qui avait appartenu à l'ours marin (*phoca ursina*), et qui avait été rapportée du cap de Bonne-Espérance par M. Lalande"; also his brother G. Cuvier, in 1823,[2] says he had received from M. Delalande "deux squellettes de jeune âge, et une tête adulte de cette espèce" from the Cape; this adult skull he describes and figures (*op. cit.*, pl. xviii, fig. 5). As these were the only skulls of this genus in the Paris museums at the time F. Cuvier established *Arctocephalus*, it must be assumed, aside from the evidence afforded by the figure, that his type was not *Phoca ursina* Linn., but the Fur Seal of the Cape of Good Hope, referred to by F. Cuvier[3] as the "O. [tarie] de Delalande," and later named *Arctocephalus delalandii* by Gray.[4] It had, however, been previously described by Thunberg in 1811 as *Phoca antarctica*.[5] The type of *Arctocephalus* F. Cuvier is thus *Phoca antarctica* Thunberg = *Arctocephalus antarcticus* (Thunb.) Gray.[6]

GENERIC CHARACTERS. — Facial portion of skull slender, elongated, pointed, gently declined. Molars $\frac{6-6}{5-5} = \frac{12}{10}$, large in comparison with those of *Callotaria*.

Arctocephalus is well distinguished from *Callotaria*, the only other genus

of Fur Seals, by the slenderness and declivity of the rostral portion of the skull and the much more elongated and relatively narrower general form of the entire skull. The cranial differences between these two groups are, however, not nearly so great as those which separate *Otaria* from *Eumetopias* and *Zalophus*. Dr. Peters, in his last synopsis of the Eared Seals, referred all of the Fur Seals to the genus *Arctocephalus*, and placed all the Hair Seals, except *Otaria byronia*, in the genus *Eumetopias*, thus recognizing only three genera of Otaries — *Otaria*, *Eumetopias* and *Arctocephalus*.

The number of species of *Arctocephalus*, as well as their nomenclature, has been a subject much in dispute, owing to lack of sufficient material to determine the status of the supposed species, and to the unsatisfactory basis of many of the earlier names. Peters, in 1877, recognized seven species of southern Fur Seals, but several of them rest on very unsatisfactory evidence. In 1892[1] I considered that six were fairly entitled to recognition; another, *Arctocephalus townsendi* Merriam, had not then been described. They are, adding the latter, as follows:

1. *Arctocephalus townsendi* Merriam. Guadalupe Island, off Lower California.

2. *Arctocephalus philippii* (Peters). Islands of Juan Fernandez and Mas a Fuera, and probably adjacent coast and islands of western South America.

3. *Arctocephalus australis* (Zimm.). Falkland Islands, Straits of Magellan, and probably South Georgian Islands.

4. *Arctocephalus antarcticus* (Thunb.). West coast of South Africa and adjacent islands.

5. *Arctocephalus gazella* (Peters). Kerguelen Island, and St. Paul and Amsterdam Islands, and probably the Crozet Islands.

6. *Arctocephalus forsteri* (Lesson). Coasts of New Zealand, Australia and Tasmania, and the islands to the southward and eastward.

Very little new light has since been thrown upon the subject, as regards the number and exact definition of the species. Facts of considerable importance having an indirect bearing on the matter have been developed through the Fur Seal Investigations of the seal herds in Bering Sea and the North Pacific; it having been established that the several herds which frequent respectively for breeding purposes the Pribilof Islands, the Kurile

[1] Proc. Fur Seal Arbitration, Vol. II, Appendix to Case of U. S., I, 1892, pp. 373–375.

Islands, and the Commander Islands, have separate feeding as well as breeding grounds, and do not mingle even during migrations; and also that the animals composing these separate herds are so far differentiated in external and other characters as to be considered worthy of recognition in nomenclature under separate names. Thus instead of the northern Fur Seals being all referred as formerly to a single species, they are considered as separable into three closely related species, under the names respectively, of (1) *Callotaria ursina* (Linn.) of Bering Island, the real Sea Bear (*Ursus marinus*) of Steller; (2) *Callotaria alascana* (Jordan & Clark) of the Pribilof Islands; and (3) *Callotaria curilensis* (Jordan & Clark).[1] The differences, so far as known, separating these forms are sufficient to render even their peltries distinguishable. This being the case it is more than probable that the southern Fur Seal herds that congregate at different breeding resorts would also show similar differentiation, if material representing them could be brought together in sufficient amount for satisfactory comparison. It does not, for example, seem probable that the Fur Seals of the Galapagos Archipelago can be strictly the same as those breeding on the Falkland Islands,[2] or even those of Juan Fernandez and Mas a Fuera Islands; or that the herds that formerly resorted in immense numbers to the Shetland, South Georgian and other Antarctic Islands south of Cape Horn may not have presented minor differences from those whose breeding resorts were in much lower latitudes. In the absence of satisfactory material, however, for such comparison the Fur Seals of southern South America and adjacent islands will be treated in the present connection as belonging to two species, under the names *Arctocephalus australis* (Zimm.), of which the type locality is the Falkland Islands, and *Arctocephalus philippii* (Peters), of which the type locality is Juan Fernandez Island. Both species are represented in the material at hand by fifteen skulls, of which four are referable to *A. australis* and eleven to *A. philippii;* ten of the latter are from the Galapagos Archipelago, while one purports to have come from "Straits of Magellan."

The two South American species may be readily recognized by their marked cranial differences, the skull of *A. australis* having the rostral

[1] Jordan and Clark, Report Fur Seal Investigation, I, 1898, p. 45, and III, 1899, p. 3.

[2] Since this article was prepared, early in 1902, the Galapagos Fur Seal has been separated as *Arctocephalus galapagoensis* by Heller (Proc. Cal. Acad. Sci., 3d Ser., Zoöl., III, 1904, p. 245), but on very unsatisfactory evidence of its distinctness. See further, p. 134.

portion very short with short nasals, while the same part in *A. philippii* is relatively greatly lengthened, with correspondingly long nasals. In brief, *A. australis* is a *short-nosed* species and *A. philippii* a *long-nosed* species. These features also involve the whole contour of the skull, so that one is markedly brachycephalic and the other strongly dolichocephalic. The two species are so distinct that they represent two very good subgenera, as recognized by Peters in 1866, *A. philippii* being the type of his subgenus *Arctophoca*.

A very distinct species of this genus, not previously known to exist north of the equator, was described by Dr. Merriam, in 1897, from Guadalupe Island, off the coast of Lower California, from weathered skulls collected by Mr. C. H. Townsend. These skulls, kindly loaned to me for comparison with skulls of *Arctocephalus* from the Straits of Magellan and the Galapagos Archipelago, prove of such interest that it has been deemed desirable to give figures of them for comparison with those of their southern allies, and to republish in this connection Dr. Merriam's original description and historical summary of this nearly extirpated animal, with additional historical matter.

Arctocephalus (Arctophoca) gracilis Nehring, Arch. f. Naturg., 1887, i, 92, pl. ii (skull, young). Rio Tramandahý, Rio Grande do Sul, Brazil.

? Otaria brachydactyla Philippi, An. Mus. nac. Chile, I, Zool., 1892, 6, 43, pl. xiii, fig. 2, animal, pl. xxii, skull, very young, with the milk dentition; length of animal, 900 mm. Chonos Archipelago.

Arctocephalus falclandicus var. *gracilis* Nehring, Sitzungsb. Ges. Naturf. Freunde zu Berlin, 1877, 142—coast of Rio Grande do Sul, Brazil.

External Characters.—Pelage of two kinds of hair—long, coarse, blackish overhair tipped with gray or yellowish gray, giving a grizzled effect, except on the ventral surface, where the hairs are without gray tips; beneath this is the thick soft brownish underfur, lighter at the tips and darker basally.

In the absence of specimens it is almost impossible to give a satisfactory description of the external characters of the South American Fur Seals. What the external distinctions may be, can be determined only by

an examination of a good series of specimens from various localities. In general coloration, ears and foot structure, they do not appear to differ greatly from the northern species, although they must differ markedly (in life) in physiognomy and more or less in the color and texture of the pelage.

Skull.—Skull short and broad, the brain-case subquadrate, the anteorbital region very short, not greatly depressed, the very short nasals only very slightly sloping and the extreme front border slightly raised, giving a marked retroussé effect; zygomatic arches broadly expanded, the palate strongly concave and the posterior nares narrow; sagittal crest slightly developed. The skull as a whole is shorter and broader than in *A. philippii*. The unworn teeth are distinctly tricuspid, there being a distinct, low, pointed cusp at the anterior base of the main cusp, and a similar one on its posterior border. Teeth relatively much smaller than in *A. philippii*.

The following table of comparative measurements (p. 128) of four skulls each of *A. australis* and *A. philippii* serve to illustrate the chief points of cranial difference in the two species.

General History.—The first introduction of the present species into the literature of natural history appears to have been made by Pennant in 1781, in his "History of Quadrupeds" (Vol. II, p. 521), where, under the name "Falkland Isle Seal," he described a young fur seal in the Museum of the Royal Society sent "from the *Falkland isles*." Although his description is very incomplete, it has always been considered as referable to the Falkland Island Fur Seal. Pennant's account became the following year (1782) the basis of Zimmermann's *Phoca australis*. In 1800 the same description formed the basis of *Phoca falklandica* Shaw, under which name the species was commonly known till 1880, when Zimmermann's long-forgotten earlier name was revived for it.

In 1828 Lesson renamed *Phoca falklandica*, calling it *Otaria shawi*, and also, in the same year, named the "Otarie de Péron" of Blainville, based on another young specimen from the Falkland Islands ("Iles Malouines"), *Otaria hauvillii*, making the third name based on young specimens of the Falkland Island Fur Seal. The two Cuviers and various other writers had previously referred the Southern Fur Seals to *Phoca ursina*, or to some vernacular equivalent, believing they were not specifically different from the Fur Seals of the North, the *Ursus marinus* of Steller.

Dr. J. E. Gray, in 1859, based the name *Arctocephalus nigrescens* on a young skull from the Falkland Islands, a "species" he continued to recognize in all his later works and papers on the Eared Seals, but which by other writers has been quite as uniformly referred to *Arctocephalus falklandicus*. In 1874 the same author based the name *Euotaria latirostris* on a skull also supposed to have come from the Falkland Islands, making the third species recognized by him from these islands. In 1873 Mr. A. W. Scott added still another synonym by avowedly renaming, as *Arctocephalus grayi*, the *A. falklandicus* of previous authors. In 1887 Nehring based the name *Arctocephalus gracilis* on skulls of young examples taken on the coast of Rio Grande do Sul; and in 1892, Philippi described and figured a very young specimen, under the name *Otaria brachydactyla*, from the Chonos Archipelago, which may or may not be referable here.

[1] Only five molars instead of the normal number, six.

The locality is against such a reference. The skull, as figured, shows the milk dentition, and the short nasals, which give it a resemblance to the skull of *A. australis*, may be due to its extreme immaturity. The description and figures are not sufficient for the satisfactory identification of the alleged species.

Although hundreds of thousands, and probably millions, of these animals have been slaughtered for their peltries, no proper or adequately satisfactory account has been given of the external characters of the species, descriptions of which have been almost entirely based on skulls alone, owing to the absence in museums of the skins of this species.

One of the most detailed accounts yet published is that given by Hamilton in the "Annals of Natural History" (Vol. I, Oct. 1838, pp. 81–95, pl. iv, animal), and republished in part in his "Amphibious Carnivora" (Jardine's Naturalists' Library, VI, 1839, pp. 271–279, pl. xxv). Under the title "Observations on the Fur Seal of Commerce," he gave a critical and discriminating review of the literature of the subject, and described "the Fur Seal of Commerce" in considerable detail from two stuffed specimens presented by Captain Weddell to the Museum of the University of Edinburgh, with extracts from Captain Weddell's[1] account of its habits. It is, however, not stated whether the specimens came from the Falkland or South Shetland Islands, though probably from the latter, judging from Weddell's narrative.

The fullest recent account of the Falkland Island Fur Seal is that given by Turner in the "Zoölogy of the Challenger Expedition" (part lxviii, 1888, pp. 39–41). The skull, on the other hand, has been described and figured by Gray (as *Arctocephalus nigrescens* and *Euotaria latirostris*—see bibliographical citations above), and recently by Burmeister and Turner. Burmeister's plate x of the second livraison of the Mammals of the Atlas to his "Description Physique de la République Argentine" (1883) gives a view of the animal, an adult male, with three views of its skull; also three views of the skull of a young animal, and figures of the hyoid apparatus and the bones of the fore and hind feet; but there is no information as to the place of capture of the specimens figured, though presumably they came from Lobos Islands, Uruguay. Turner, in the "Zoölogy of the Challenger Expedition" (*l. c.*, pl. vi), has also figured the skull and other

[1] Voyage to the South Pole, London, 1825, pp. 137, 140. See also Allen, *l. c.*, pp. 378, 379 where Weddell's account is again quoted.

parts of the skeleton (*l. c.*, pl. vii). As, however, Dr. Turner's figures are not altogether satisfactory, the teeth especially having been badly drawn, the accompanying illustrations (Plates XV, Fig. 1; XVI, Fig. 2; XVII, Fig. 2) may not be superfluous.

Geographical Distribution. — This species is unrepresented in the collections of the Princeton Patagonian Expeditions, nor is any very definite reference made to it in Mr. Hatcher's "Narrative." Mr. Barnum Brown, however, observed it off the coast of Tierra del Fuego, and has kindly prepared the following account of his observations. He says (MSS. notes): "Fur Seals were seen in considerable numbers on the south coast of Tierra del Fuego, but they were not observed off the coast of Patagonia. One herd, estimated to contain 1500 head, was seen near Cape Hall, west of the Strait of Le Maire, and two smaller herds were seen south of Lenox Island, having less than 200 individuals each. These seals are poached by a few natives, but owing to the abrupt, rugged rocks they are seldom found on shore and cannot be driven to a killing ground. The Argentine Government sends a gunboat to these waters once a month to keep off poachers."

The species ranges northward along the Patagonian coast to the mouth of the Rio de la Plata, where it has been long known to frequent the small islands off Maldonado. An out-lying colony was also reported by Nehring[1] in 1887 as found on the coast of Rio Grande do Sul, Brazil, at the mouth of the Rio Tramanduhý; and the same year, through Dr. Nehring, Dr. Goeldie[2] made known the capture of specimens at Ponta Negra, in the neighborhood of the city of Rio de Janeiro, Brazil, — doubtless, however, an exceptional occurrence.

The breeding haunts of this species, as is well known, formerly included the Falkland Islands, New Year's Island, Staten Land, Desolation Islands, and other islands and coasts off the southern portion of South America, and probably the more southern South Shetland, South Georgian, and Sandwich groups. They doubtless still resort to most of these localities, but only in small numbers in comparison with their former abundance.

The material used in the present connection consists of a series of skulls in the United States National Museum, from the Strait of Magellan, which are, however, without definite localities.

Otaria (*Arctophoca*) *argentata* Philippi, Monatsb. Akad. Berlin, 1871, 560, pll. i, ii, skull, Juan Fernandez Island. Considered by Peters to be the female of *Arctocephalus philippii*, *l. c.*, 1871, 563.

Otaria argentata? Philippi, An. Mus. nac. Chile, I, Zool., 1892, 38, pl. xx, animal.

Otaria leucostoma Philippi, An. Mus. nat. Chile, I, Zool., 1892, 6, 46, pl. xxiii, animal. Mas a Fuera. Young; length 690 mm.

Orctocephalus galapagoensis Heller, Proc. California Acad. Sci. (3), Zoöl., III, 1904, 245–248. Wenman Island, Galapagos Archipelago.

External Characters.[1] — Above blackish gray, more yellowish gray on the head and neck; brownish black below, proximal portion of the limbs rusty brown; lips and chin rusty brown; mustachial bristles in six rows, part wholly black, part wholly white, and part black with the basal portion white. The long overhair rusty brown basally, with rusty yellow tips on the back, head, and neck, and on the ventral surface uniform brownish black or with the tips ferruginous. The thick underfur is fer-

[1] In the absence of specimens, a free translation of Dr. Peters's original description of the external characters is here given. The cranial measurements (p. 128) are taken from skulls from the Galapagos Archipelago.

ruginous (rostroth). The hair on the upper part of the neck has a length of 22 mm., on the middle of the back, 18 mm., and on the middle of the belly, 11–12 mm. The thick, smooth-lying short hair on the dorsal surface of the fore limbs extends only to the middle of the hand and basal portion of the phalanges, which are tipped with very small nails. The distribution of the hair on the upper surface of the hind limbs is the same as on the fore limbs. The nail on the outer toe of the foot is small, flat and short; that on the inner toe somewhat longer. The three middle toes have well developed nails. The skin flap at the end of the toes is largest on the outer toes and smaller on the middle toes, being broadest on the outer toe.

Total length from the end of the nose to the end of the tail, 1570 mm.; length of the ear 36; length of the tail, 35; length of the palm, 300; length of the sole, 350; length of the membrane on the middle toes, 90–105; length of the skull, 235. (For further cranial measurements see the table under *A. australis*, p. 128.)

The specimen described by Dr. Peters, as summarized above, is a young adult male, as shown by the illustrations of the skull, in which the sagittal crest is only slightly developed. The ear is apparently a little shorter than in *A. australis*, but in other respects there are no very marked external differences between *A. australis* and *A. philippii*.

Skull.—Skull long and narrow, the posterior part much narrower than in *A. australis*, though the skull as a whole is much longer; rostral portion also narrower, longer and much more sloping; nasals about one third longer and much narrower; dentition much heavier, and the accessory cusps generally wholly absent or rudimentary; palate nearly flat, not vaulted as in *A. australis;* sagittal crest strongly developed, reaching a height of 28 mm. in old males and extending forward to the postorbital processes, as in *Zalophus*, and reaching as great a degree of development.

Geographical Distribution.—The type locality of *Arctocephalus philippii* is the Island of Juan Fernandez, off the Coast of Chili. In the material at present available there is a single skull labelled as from the Straits of Magellan, and one from "Patagonia," probably Paraca Bay; all of the other eight skulls are from the Galapagos Archipelago, two being from Jarvis Island and six from Hood Island. It would thus appear that *Artocephalus philippii* ranges from the Straits of Magellan northward along the west coast of South America to the Galapagos Archipelago.

Among their noted resorts, from which hundreds of thousands have been taken by the sealers, are Mas a Fuero and Juan Fernandez Islands, the St. Felix, St. Ambrose, and St. Mary's Islands, and Albemarle and other islands of the Galapagos group.[1] Apparently they formerly bred in large numbers at most of these resorts, where apparently a few are still found. There are also numerous records of their capture at many points on t' e coast of Chili, at the Chincha Islands, and in the Bay of Callao on the coast of Peru.

General History.—Under the name *Phoca porcina* Molina, in 1782, described an eared seal, but whether it was a species of *Otaria* or an *Arctocephalus* it is impossible to determine. It is so very imperfectly described that it must be considered as undeterminable.

Tschudi, in his "Fauna Peruana" (1844–1846), published under the name "*O*[*taria*] *aurita* Humboldt," a drawing and a manuscript description of a young eared seal from the San Lorenzo Island, in the Bay of Callao, communicated to him by Humboldt. There is nothing in the description to show whether it was a hair seal (*Otaria*) or a fur seal (*Arctocephalus*).

The first name unquestionably referable to a fur seal from the west coast of South America is *Otaria philippii* Peters (1866), based on a skin and skull of a young adult male from Juan Fernandez Island, of which he gave a detailed description and excellent figures (natural size) of the skull. At the same time he referred it to a new subgenus *Arctophoca*, on the basis of its having only five teeth in the upper premolar-molar series, and the palate deeply emarginate. Neither of these features was normal, the antepenultimate tooth having fallen out (a partly obliterated alveolus is clearly shown in Peters's figure on the right side, and more than the normal interval on the left side), while the great emargination of the posterior border of the palate is obviously due to imperfect ossification. Both these abnormalities occur with some frequency in various species of the Otariidæ.[2]

[1] For some account of the slaughter of this species for its skins at Mas a Fuero, Juan Fernandez, and Galapagos Islands see Allen, Rep. Fur Seal Arbitr., App, to Case of United States, Vol. I, 1892, pp. 394–396. Also Townsend (for the Galapagos), Fur Seals and Fur Seal Islands of the N. Pac. Ocean (Jordan), Part III, 1899, p. 273.

[2] Of the six skulls from Hood Island, Galapagos Archipelago, four have the molars $\frac{6-6}{5-5}$ and two have them $\frac{5-5}{5-5}$, in these two instances with no indication that there were ever any more. In another skull there is a supernumerary denticle between the 5th and the 6th teeth on each side.

In 1871 Philippi based the name *Otaria* (*Arctophoca*) *argentata* on a specimen from Juan Fernandez Island which Dr. Peters and subsequent writers generally have considered as representing the female of *A. philippii*. The same author in an article entitled "Las Focas Chilenas" (An. Mus. Chili, 1892, pp. 52, pll. 23) has recognized five or six species of fur seals from the coast and islands of Chili, all apparently referable to those previously known from the Chilian coast. Among these are two, both based on immature specimens, described as new, namely (1) *Otaria brachydactyla*, from the Chonos Archipelago, founded on a suckling pup still retaining the milk dentition, and too immature for determination by the description and figures (see *antea*, p. 126); and (2) *Otaria leucostoma* from Mas a Fuera, of which the skull is not figured. It is apparently a female or a young male of *Arctocephalus philippii*.

In 1904 the Fur Seals of the Galapagos Archipelago were separated by Heller (*l. c.*) as a distinct species under the name *Arctocephalus galapagoensis*, on the basis of certain supposed cranial differences distinguishing it from *A. philippii*. His comparison must have been made with Peters's description and figures of the skull of *A. philippii*, which I had already considered with care in reference to a good series of Galapagos skulls, without feeling myself warranted in making the separation later proposed by Mr. Heller. His alleged characters—"wider skull, both the zygomatic and mastoid measurements being considerably greater, and by longer snout and mandible"—are not evident. While his measurements of an "old adult" male skull are larger than those given by Peters, it must be recalled that the type skull of *A. philippii* was, while "full-grown," "not very old."[1] The differences in size and proportions are only what might be expected in skulls of the same species of corresponding ages. While the Galapagos animal may very naturally be different on geographical grounds, from that of the Juan Fernandez Islands, as already intimated (*antea*, p. 123), any differences that may exist can be shown only by direct comparison of satisfactory material from

A skull from Jarvis Island, Galapagos Archipelago, has six teeth on the left side and only five on the right, set in close juxtaposition.

The emargination of the palatal border, in varying degree, is a not very uncommon condition in Pinnipeds which have normally the palatal border truncate or only slightly concave.

[1] " . . . dem Schädel eines augsgewachsenen, aber noch nicht sehr alten männlichen Exemplars."—Peters, Monatsb. Akad. Berlin, 1866,p. 276.

the two localities. Until this has been done it seems premature to treat the two forms as specifically different.

Arctocephalus townsendi Merriam.

(Plates XVIII, XIX and XX, Skulls.)

[*Arctocephalus* sp.] Allen, Gill and Merriam, Fur Seal Arbitration, Append. to Case of the United States, I, 1892, 586. Announcement of the discovery of a species of *Arctocephalus* on Guadalupe Island, Lower California.

Arctocephalus sp. nov. Allen, *ibid.*, 373, making the same announcement, with historical comment on the occurrence of Fur Seals off the coast of Mexico, Lower California and southern California.

Arctocephalus townsendi Merriam, Proc. Biol. Soc. Washington, XI, 1897, pp. 175–178, original description. — Townsend, Fur Seals and Fur-Seal Islands N. Pac. Ocean (Jordan), III, 1899, 269–272, habits and statistics of capture.

In the general form the skull of *A. townsendi* is much nearer that of *A. philippii* than that of *A. australis*. In cranial characters *townsendi* differs from *philippii* much as *philippii* does from *australis*, but the distinctive features of *philippii* are carried less far in *townsendi*, and other differences are added. Especially distinctive are: (1) the greater narrowness of the skull, particularly of the rostral portion; (2) the much narrower and more depressed palate; (3) the more flattened audital bullæ; and (4) the somewhat smaller size and slenderer form of the skull. The external differences are not known, *A. townsendi* being thus far known only from more or less imperfect skulls.

I am indebted to Dr. C. Hart Merriam, the describer of the species, for an excellent photograph of the palatal aspect of the type skull (an old male), here reproduced (natural size) in Plate XVIII, and a "young adult" female skull, here figured (natural size) in Plates XIX and XX. A comparison of Plate XVIII (palatal view) with Plate XVII (palatal views, ¾ nat. size) will serve to illustrate some of the striking differences that distinguish *A. townsendi* from both *A. philippii* and *A. australis*. For further descriptive details it is sufficient to transcribe Dr. Merriam's original description, as follows:

"*Type Locality.*—Guadalupe Island, off Lower California. Type No.

83617, ♂ ad., U. S. National Museum. Collected on the beach on west side of Guadalupe, May 22, 1892, by C. H. Townsend.

"*Cranial Characters.*—Contrasted with skulls of *Arctocephalus* (*australis* or *phillipi* [=*philippii*]) from the Galapagos Islands, skulls of *A. townsendi* differ in somewhat smaller size; much shorter rostrum; shorter nasals; larger and more freely open incisive foramina; heavier and shorter ascending branches of premaxillæ, which do not push backward along the nasals as in *australis* [=*philippii*]; smaller, flatter and smoother audital bullæ; *much narrower* and more deeply excavated palate; narrower postpalatal notch; broader and heavier jugals; broader zygomatic processes of maxillæ, which are *expanded to form a broad floor under* the anterior half of the orbit; larger, broader, and more rounded anterior nares in the male, and absence of sagittal crest between frontals.

"The most important characters are the exceedingly narrow and excavated palate, flat audital bullæ, short and thick ascending arm of premaxilla, and broadly expanded zygomatic root of maxilla, forming a floor under the anterior half of the orbit. There are also tooth characters: the first upper molar (5th molariform tooth) is mainly posterior to plane of anterior root of zygoma; both upper true molars are double rooted, and the last upper premolar is incompletely double rooted.

"In the female of *townsendi* the narrow and deeply excavated form of the palate is even more emphasized than in the male, and the postorbital constriction is very much narrower than in the female of *australis* [=*philippii*]."

"Measurements of Male Skull of *Arctocephalus townsendi* (the type).

"Greatest basal length (gnathion to occipital condyles)	256
Basal length (gnathion to basion)	243
Basilar length of Hensel (basion to incisors)	233
Palatine length (gnathion to postpalatal notch)	120
Postpalatal length (postpalatal notch to basion)	125
Zygomatic breadth	151
Lateral series of teeth (canine to last molar inclusive)	88
Distance between canines	22.5
Distance between 3d pair of molariform teeth	22.5
Breadth (anteroposterior) of zygomatic root of maxilla between inferior lip of antorbital foramen and orbit	21"

The Guadalupe Island Fur Seal, though now commercially extinct, being reduced to a few individuals, was formerly so abundant as to have

formed the basis of a profitable Fur Seal fishery, carried on at intervals for many years, at several groups of islands off the western coast of Mexico and Lower California. The history is so interesting, as well as important, that it may well be here transcribed for convenient future reference.

The first notice of this seal as a distinct and undescribed species is a note written in June, 1892, and signed jointly by Dr. Gill, Dr. Merriam, and the present writer, as given below, and published the same year in the report of the "Fur Seal Arbitration, Appendix to the Case of the United States," Vol. I, p. 586, but not available for public reference till 1895. This note, entitled "The Fur Seal of Guadalupe Island, off Lower California," is as follows:

"For many years it has been known that fur-seals breed at Guadalupe Island, where formerly large numbers were killed annually for their skins. Two thousand were secured as late as 1883, since which time small numbers have been taken nearly every year. Inasmuch as the Northern fur seal (*Callorhinus ursinus*) is not known to breed south of the Pribilof Islands, but occurs in winter off the coast of northern California and passes north in the spring, it seemed important to determine the species of fur-seal inhabiting Guadalupe Island. For this purpose an expedition was sent to said island by the direction of Dr. C. Hart Merriam in May, 1892, in charge of Mr. C. H. Townsend, an assistant of the United States Fish Commission. Seven fur seals were seen near the island and one was shot by Mr. Townsend, but it sank before it could be recovered. The visit was made too early in the season to find the seals on the shore. A beach on Guadalupe Island was visited where it was known that a large number of fur seals had been killed a few years previously and four skulls were there obtained. We have carefully examined these skulls and find them to belong to a species of *Arctocephalus*, a very different kind of fur seal from that found in Bering Sea, the well-known *Callorhinus ursinus*. [Signed]

J. A. Allen,
Theo. Gill,
C. Hart Merriam."

The history of this seal probably runs back to Dampier, who, in 1686, met with seals at the Chametly and Tres Marias Islands, in latitude 23°

and 21° respectively, off the west coast of Mexico. In describing the Chametly Islands he says: "The bays about the Islands are sometimes visited with Seals; and this was the first place where I had seen any of these Animals, on the North side of the Equator, in these Seas." In writing of the Tres Marias Islands he says: "The Sea is also pretty well stored with Fish, and Turtle or Tortoise, and Seal. This is the second place on this Coast where I did see any Seal: and this place helps to confirm what I have observed, that they are seldom seen but where there is plenty of Fish."[1] Whether these seals were the California Sea Lion (*Zalophus californianus*), the California Sea Elephant (*Mirounga angustirostris*), or a Fur Seal, he has left no means of determining.

The early history of their presence on the coast of Lower California and Mexico I have detailed in another connection[2] and here transcribed.

"Formerly large numbers of fur-seals were taken at the San Benito, Cerros (or Cedros), Guadalupe, Santa Barbara, and other islands off the coast of Lower California, and also on the coast of the mainland. Though formerly abundant at all these points, they have become nearly exterminated by the indiscriminate and persistent attacks of the seal hunters.

"Until recently the fur-seals off the Lower California coast were supposed to be the same as the Alaska species, but Dr. Merriam has recently obtained skulls from the old killing grounds on Guadalupe Island which show that it is not only a different, as yet a probably undescribed species, but that it is referable to the genus *Arctocephalus*, not previously known to occur north of the equator. It is resident the whole year off the California coast, and resorts to the caves on the islands it frequents to bring forth its young. In these respects it resembles the fur-seals of the Galapagos Islands, to which it seems to be closely related.

"The following historical notes may be of interest in the present connection:

"In 1825 Capt. Benjamin Morrell cruised along the west coast of Mexico and California in search of fur-seals. Under date of May 20, 1825, he writes that he arrived at Cape Blanco, in latitude 42° 49′ N. 'Between this cape and that of Mendocino, which is in latitude 40° 17′ N. . . . there are many small islands and rocks, some of which lie 3 miles from the main. On these islands or keys I expected to find fur-seals, whereas

[1] A New Voyage Round the World, 5th ed., Vol. I, 1703, pp. 263, 276.

[2] Fur-seal Arbitration, Appendix to the Case of the United States, I, 1892, 373, 374.

I found them all manned with Russians, standing ready with their rifles to shoot every seal or sea-otter that showed its head above water.' (Morrell, Voyages and Discoveries, p. 212.) Continuing southward, 'perceiving little prospect of taking fur-seals on any part of the coast which the Russians have monopolized,' he reached Socorro Island, in latitude 18° 53′ N. 'At 6 a. m. the boats were despatched to examine the island in search of fur-seals; but returned, after a faithful inspection, without seeing more than twenty animals of that species. They saw about 300 sea-leopards and 1,500 hair-seals.'[1] (*Ibid.*, p. 213.)

"He visited Guadalupe Island earlier in the season (March 27–31), and says: 'We lay here three days, during which time we took a number of fur-seals.' A few days later he visited Cerros Island, and sent out boats to search the island, but neither seals nor sea-elephants were seen. He says: 'There are many fine fish to be caught around this island, and it was formerly a great resort for sea-elephants and fur-seals; but it now appears to be entirely abandoned by these animals.' (*Ibid.*, p. 196.) On April 8 he landed at Cenizas Island, in about latitude 30°, in search of fur-seals, but found only sea-leopards and sea-elephants, about 400 of the former and 800 of the latter. Later (April 23 to May 5) he 'examined the islands of St. Clement, St. Barbara, St. Rosa, and St. Miguel,' for fur-seals, but, he says 'without much success,' although he saw a few sea-elephants and many 'sea-leopards.' On May 11 he arrived at the Farallon Islands, of which he says: 'Many years ago this place was the resort of numerous fur-seal, but the Russians have made such havoc among them that there is scarcely a breed left. On this barren rock we found a Russian family and twenty-three Codiacks, or Northwest Indians, with their bark canoes. They were employed in taking sea-leopards, sea-horses, and sea-elephants for their skins, oil, and flesh, the latter being jerked for the Russian market on the Northwest Coast.' (*Ibid.*, pp. 108, 110.)

"Captain Scammon refers to the former occurrence of fur-seals at San Benito Islands and on the 'coast of California,' where, he says, 'many beaches were found fronting gullies, where [fur] seals in large numbers formerly gathered; and as they had plenty of ground to retreat upon, the sealers sometimes drove them far enough back to make sure of the whole

[1] Probably *Zalophus californianus*, which probably still occurs there in small numbers. *Cf.* Nelson, N. Amer. Fauna, No. 14, April 29, 1899, pp. 17, 18.

herd, or that portion of them the skins of which were desirable.' (Scammon, Marine Mammalia of the Northwest Coast, pp. 152, 154.) Unfortunately Captain Scammon's account gives no definite dates, but the period referred to must have been prior to the year 1850. He also refers, in Mr. J. Ross Browne's "Resources of the Pacific Slope" (p. 128), to Guadalupe and Cerros Islands as having been formerly favorite resorts of fur-seals and sea-elephants."

Dr. Merriam's account of the circumstances that led to the discovery of the species, and his statistical history of Fur Seal hunting within a comparatively recent period at Guadalupe Island,[1] complete the history of a species that nearly reached extinction before its existence had become scientifically known. He says:

"During the recent international discussion respecting the seals of Bering Sea, the matter of the distribution of the Northern Fur-seal (*Callorhinus ursinus*) has received closer attention then heretofore, and questions have arisen as to the southernmost range of the species in the past.

"It had been known for many years that colonies of fur-seals inhabited parts of Guadalupe and the San Benito Islands, off the coast of Lower California, and these seals were commonly assumed to be the northern species — the same that breeds in such numbers at the Pribilof Islands in Bering Sea. But it seemed to me a violation of the known laws of geographic distribution that a species adapted to the arctic climate and cold waters of Bering Sea, and even there requiring constant fogs to protect it from the feeble rays of the sun, should be able to breed under clear skies on the subtropical islands of Guadalupe and San Benito.

"During the sessions of the Bering Sea Joint Commission in February and March, 1902, I made bold to express the opinion that the fur-seal which breeds on these islands would prove to be, not the northern species belonging to the genus *Callorhinus*, but a southern species belonging to the genus *Arctocephalus*. No specimens were at hand for examination, but through the coöperation of the Department of State and Fish Commission I was enabled to send a small boat, in direct charge of Mr. C. H. Townsend, on a special mission to Guadalupe Island.

[1] A New Fur-Seal or Sea-Bear (*Arctocephalus townsendi*) from Guadalupe Island, off Lower California. By C. Hart Merriam. Proc. Biol. Soc. Washington, Vol. XI, pp. 175–178, July 1, 1897.

"Mr. Townsend sailed from San Diego on May 14, 1892, reached Guadalupe on the 16th, and remained there until the 27th. He saw seven fur seals and shot one, which sank before it could be recovered. The trip was made too early in the season to find the seals on shore. A locality was visited where it was known that a large number had been killed a few years previously, and here four skulls were obtained. These skulls were immediately sent to Washington, and on their arrival, were examined by Dr. J. A. Allen, Dr. Theodore Gill and myself, and proved, as had been suspected, to belong to the genus *Arctocephalus*. A joint note to this effect was published by us in the "Fur Seal Arbitration, Appendix to the Case of the United States," Vol. I, p. 586, 1892. In the same volume (p. 373) Dr. Allen expresses the belief that the skulls in question represent an undescribed species. The northernmost locality from which the genus had been previously recorded is the Galapagos Islands under the equator, about 2,500 miles southeast of Guadalupe.

"In his manuscript report on the Guadalupe trip Mr. Townsend states: 'Guadalupe Island is thoroughly volcanic and there are caves by the dozen along every mile of the shoreline which were once the retreats of thousands of fur seals. On the afternoon of May 17 we saw four seals swimming some distance off shore. Two of these we believed to be fur seals, but could not get within shooting distance, although we tried for an hour. The other two, seen later, were undoubtedly *Zalophus*. No seals whatever were found on the rocks. . . . On May 22 we examined SW Point and the three islands or rocks south of it. On the most southerly rock we found a band of *Zalophus*, about thirty in number, hauled out. There was no fur seals among them. Passing the point, we continued, pulling in the dory, the schooner lying to off shore, up the west side of the island about eight miles, where we anchored. In the evening we visited the spot where Borges and Sisson had killed two or three hundred fur seals about ten years before. Only a few weather-worn skulls were found, which we gathered for shipment to Washington. The next day, May 23, we hunted along shore, in the boat as usual, as far as the next point south of NW Point about six miles, the schooner keeping well off shore. At 10 A.M., near the outlying rocks off this point, we found what seemed to be a male fur seal, perhaps about four years old, asleep on the water with his fins held aloft in the manner so characteristic of these animals. I got a pretty fair shot with the rifle but missed. Half an hour later I

shot a female fur seal, killing it instantly. Before we could get the hook on it, it sank below our reach, although only three boat-lengths away when shot. The water was perfectly clear and we could see the animal sinking when we reached the bloody spot on the water. It began to sink *immediately* when shot. With an extra long hook we might have reached it. We remained in the neighborhood for an hour, but no more seals were seen. While lying to with the vessel about two miles off this point the Captain saw two fur seals from the vessel, but was powerless to try getting them. It was on the rocks at this point that Capt. Hunt had killed a pup fur seal the year before (1891).'

"In addition to his own observations Mr. Townsend collected from California sealers some very important information respecting the abundance of the Guadalupe fur-seal and the numbers killed in recent years. This may be summed up as follows:

"In 1880 Capt. Geo. W. Chase, of San Diego, made several trips to Guadalupe for fur-seals, which he found 'tightly packed in the caves and holes [in the rocks].' He generally fired at their eyes in the darkness of these places, but sometimes used candles. His skins sold for $15 each, from which he made $2,200 in 1880. The same man (Capt. Chase) stated that about a year earlier a Mr. Borges sold his catch of Guadalupe seal-skins at San Francisco for over $20,000 (the rate being $10 to $15 per skin).

"In 1883 Capt. Geo. E. Wentworth killed about 2,000 fur-seals on Guadalupe. Captain Wentworth states that several other vessels were there at the same time, and that the Guadalupe fur-seal was practically [commercially] exterminated that year — 1883.

"In 1890 Capt. Nelson told Mr. Townsend that he had killed fur-seals with more or less regularity every year on the exposed shingle beach at the northwest end of Guadalupe Island, where he pursued them into the caves and killed them with clubs.

"In 1891 Geo. M. Hunt, of San Diego, visited Guadalupe in December for the purpose of sealing and killed 5 fur-seals — 4 adults on the east side and one pup on the northwest side. A few others were seen off shore."

In a paper published by Mr. Townsend in 1899,[1] he gives (*l. c.*, p. 272)

[1] Pelagic Sealing with Notes on the Fur Seals of Guadalupe, the Galapagos, and Lobos Islands. By Charles H. Townsend, U. S. Fish Commission. The Fur Seals and Fur-Seal Islands of the North Pacific Ocean (Jordan), Part III, 1899, pp. 223–274, pll. xxii–xxxv.

in detail the information above summarized by Dr. Merriam, and adds, on the authority of Mr. A. W. Anthony, a well known naturalist, that 36 fur-seals were taken at Guadalupe in 1893, and 15 in 1894. He gives also statistics for the years 1876 to 1894, and adds: "This incomplete record accounts for 5,557 fur-seals killed at Guadalupe between 1876 and 1894."

Family *MUSTELIDÆ.*

This family, so far as known, is represented in Patagonia by only three genera, a Skunk (*Conepatus humboldti*), the Weasel-like *Lyncodon patagonicus*, and two species of Otter (*Lutra*). Two other species, the Tayra (*Tayra barbara*, or a form of it), and the Grison or Huron (*Galictis vittata*) nearly reach our borders, the former occurring, according to Burmeister, as far south as the Grand Chaco in Argentina, and sparingly in Paraguay, and the latter as far south as the northern part of Patagonia. The true Weasels (genus *Putorius*) occur in northern South America, and as far south as Peru in the Andes, but are absent from the more southeastern parts of the continent.

Genus CONEPATUS Gray.

Conepatus Gray, Charlesworth's Mag. Nat. Hist., I, Nov. 1837, 581. Type, and only species, *Conepatus humboldti* Gray, sp. nov. — Howell, N. Amer. Fauna, No. 20, 1901, 20 (footnote). — Thomas, Ann. & Mag. Nat. Hist. (7), VIII, Dec. 1901, 528 (in text).

Thiosmus Lichtenstein, Abhandl. Akad. Wissen. Berlin, 1836 (1838), phys. Kl., 270. No type = *Conepatus* + *Marputius* Gray, 1837.

The genus *Conepatus*, taken in the broad sense for the bare-nosed skunks in general, ranges from the southern border of the United States southward to the Straits of Magellan. The group proves, however, divisible into three subgenera — *Conepatus* (s. s.), *Marputius* Gray,[1] and *Oryctogale* Merriam.[2] The latter includes most of the bare-nosed skunks of the United States and Mexico; *Marputius* includes certain Mex-

[1] Type, *Mephitis chilensis* (= "*Mephitis chilensis* Geoff. Inhabits Chili. Brit. Museum." According to Thomas (Ann. & Mag. Nat. Hist. (7), VIII, Dec. 1901, 528), the "type was what Gray called '*Mephitis chilensis* Geoff.'; but his specimen (B. M. 68*a*) proves to be not the Chilian Skunk (*Conepatus chinga*, Mol.), but the Brazilian one and the actual type of Lichtenstein's *Mephitis amazonica*."

[2] Type, *Conepatus leuconotus* (Licht.) from Vera Cruz, Mexico. *Cf.* Merriam, Proc. Biol. Soc. Washington, XV, p. 161, Aug. 6, 1902.

ican, Central American and South American species, leaving *Conepatus* restricted apparently to the Patagonian and allied species of southern South America. The geographical limits of these several groups, however, have not been worked out, and the material now available does not permit me to throw much light on the subject. As shown by Thomas (*l. c.*) in opposition to a suggestion by Howell (*l. c.*), the name *Thiosomus* is not available for use in this connection, being antedated by both *Conepatus* and *Marputius* of Gray, in whatever sense *Thiosmus* may be construed.

CONEPATUS HUMBOLDTI Gray.

(Plate XXII, Skulls.)

Conepatus humboldti Gray, Charlesworth's Mag. Nat. Hist., I, Nov., 1837, 581. Straits of Magellan.—Milne-Edwards, Miss. du Cap Horn, VI, Zool., 1890, 6–14, pl. i (animal), pl. vii (skull).—Merriam, Proc. Biol. Soc. Wash., XV, 165, Aug. 6, 1902 (in text).—Prichard, Through Heart of Patagonia, 1902, 260.

Conepatus nasutus, var. 2. *humboldti* Gray, P. Z. S., 1865, 146. "Hab. Magellan Straits."

Conepatus nasutus, var. 3. *chilensis*, Gray, P. Z. S., 1865, 146, in part; not *Marputius chilensis* Gray, 1837.

Mephitis patagonica Lichtenstein, Abhl. Akad. Wiss. Berlin, 1836 (1838), 275, Patagonia = *Conepatus humboldti* Gray.—Cunningham, Nat. Hist. Strait Magellan, 1871, 109. Sandy Point, Patagonia.

Conepatus castaneus Gervais & D'Orbigny, Voy. Amer. Mérid., Mamm., 1850, 19, pl. xii.

Adult Female (winter).—General color above reddish brown with two longitudinal stripes of white as follows: Two bands of white, united on the head into a transverse band in front of the ears, pass, one on either side, from the head to the base of the tail; between these a median band of chestnut, extending from the crown onto the basal fifth of the tail; this band is dark chestnut on the nape and shoulders, then light yellowish chestnut to the hips, and again darker on the lower back, rump, and base of tail; sides of the body dark chestnut brown; ventral surface still darker, blackish brown, darkening to black on the anal region and base of the tail; fore and hind limbs blackish brown; ears small, heavily clothed, blackish brown like the head; tail rather short but very broad, basally chestnut above and blackish below, then grizzled white and black-

ish above, with a broad, ill-defined subterminal band of blackish and tipped with white; below with two indistinct bands of black; claws white, fore claws very long.

This is a very old female, as shown by the skull. Two younger specimens are similar, except that the dark median dorsal band is blackish brown instead of chestnut, and the sides, underparts, and limbs are also much darker, almost black. A third somewhat older specimen is rather lighter, with a faint tinge of chestnut on the median band and sides. It would thus appear that the general color lightens with age, and that the light brown tints characterize more particularly old adults, which sometimes have the median band light chestnut and the upper portions of the sides of the body chestnut brown.

The tail, in all of the specimens, is composed of two kinds of hair, as respects length and color—long hairs wholly white, and shorter hairs with the apical portion black, which latter form the subapical black band of the tail, beyond which the tips of the wholly white hairs project for about 30 to 35 mm., forming a broad terminal white fringe. In the old specimen, described above in detail, there are two broad black bands in the tail, a subapical and a subbasal, both distinctly visible on the lower surface of the tail, but only the outer one well defined on the upper surface. A close examination shows that both bands, while quite regular and well defined as seen from below, are composed of hairs that are white basally and black apically, those forming the proximal band being only about half the length of those which constitute the subapical band. They are probably a new set of hairs, growing out to replace the longer ones.

Measurements.—Old female (No. 99270, U. S. Nat. Mus., Rio Gallegos, Jan. 18): Total length, 570 mm.; tail vertebræ, 200; hind foot, 56; longest fore claw, 18; lateral tail hairs, 140–150. Milne-Edwards gives the length of the type of *Conepatus castaneus* as: Head and body, 360; tail 180 (= total length, 540); hind foot 50; and of his Santa Cruz specimen as: Head and body, 410; tail, 110 (= total length, 520); hind foot, 60.

Skull: Total length, 64; basal length, 60; zygomatic breadth, 42.4; mastoid breadth, 34.3; postorbital constriction, 17; palatal length, 25.3; post-palatal length, 29; length of nasals, 20; width of nasals at middle, 6; upper premolar-molar series, 15.4; m^3, transverse, 8; antero-posterior, 6.5; lower jaw, length, 41.5; height at coronoid, 21; lower premolar-molar series, 20. In this skull the teeth are very much worn, but there is no sagittal crest.

Another skull, sex unknown, from Santa Cruz, slightly older, but without any sagittal crest, measures as follows: Total length, 66; zygomatic breadth, 42; mastoid breadth, 35.5; postorbital constriction, 17.5; upper premolar-molar series, 17; lower jaw, length, 42, height at coronoid, 21; lower premolar-molar series, 22.

Milne-Edwards gives the principal dimensions of the skulls of his Santa Cruz specimens (No. 1), and of the three (Nos. 2–4) obtained by D'Orbigny, respectively as follows: Total length, No. 1, 68; No. 2, 62; No. 3, 65; No. 4, 58; mastoid breadth, No. 1, 38; No. 2, 32; No. 3, 32; No. 4, 33. Only one of the four skulls has a sagittal crest; this is No. 2, in which it extends as a thin lamina of bone 22 mm. in extent.

Represented by four specimens, collected by Colburn, as follows: Rio Gallegos, 2 females, one very old, the other about one fourth grown, Jan. 18, 1898; Basalt Cañons, 50 miles southeast of Lake Buenos Aires, a young female, about one half grown, April 7; Swan Lake, a female, about two thirds grown, March 5. Also a skull, collected by Mr. Brown near Santa Cruz. As already noted, the young are much darker than the adults, but the pattern of markings is closely similar in all.

This species seems to vary considerably in color individually among adults, the specimen described and figured by Milne-Edwards, collected by Mr. Lebrun near Santa Cruz, Patagonia, being much lighter in color than Mr. Colburn's specimen taken near the mouth of the Rio Gallegos, especially on the head and apical portion of the tail; while this author states that those collected by D'Orbigny and described by Gervais have all the dark portions of the body, including the ventral surface and the feet, light chestnut.

According to Mr. Brown (MSS. notes) this animal is now quite rare in southern Patagonia, though abundant at the time of its early settlement; "a few years ago, they were destroyed by some contagious disease." He says "the Indians make beautiful capas or blankets from their skins"; and adds: "I came across one of these animals one day eating an ostrich and tried to drive it away; very much to my surprise, instead of taking advantage of his natural means of defence, the little fellow bared his teeth and came after me, whereupon I beat a retreat."

Of this species Mr. Prichard says: "The Skunk is to be met with throughout the whole country, but we saw perhaps more specimens of this animal in the neighborhood of Bahia Camerones than elsewhere. I have

observed it within ten miles of the foot of the Cordillera. The skins are much prized by the Indians for the making of *capas*" (*l. c.*, p. 260).

Genus LYNCODON Gervais.

Lyncodon Gervais, Dict. univ. d'Hist. Nat., IV, 1849, 685. Type, *Lyncodon patagonicus*, sp. nov.

This monotypic genus is most nearly related to *Grison* Oken[1] (= *Galictis* Bell et auct.) and *Tayra* Oken[2] (*Galera* Gray ex Brown), but is quite distinct from either, differing in its reduced dentition, and externally by its very short tail and peculiar pattern of coloration.

Lyncodon patagonicus Gervais.

Lyncodon patagonicus Gervais, Dict. Univer. d'Hist. Nat., IV, 1849, 685; Hist. Nat. des Mamm., II, 1855, 115, fig. (dentition). — Burmeister, Descrip. phys. Rép. Arg., III, 1879, 161. — Matschie, Sitzungsb. Ges. naturf. Freunde Berlin, 1895, 171–177.

Mustela (*Putorius*) *brasiliensis* D'Orbigny, Voy. de l'Amér. Mérid., IV, Mamm., 20, pl. xiii, fig. 3 (skull).

Putois du Chili (*Mustela brasiliensis* on plate) Blainville, Ostéog., Gen. Mustela, 42, pl. xiii (dentition).

Mustela quiqui Burmeister (*nec* Molina) Reise durch die La Plata Staaten, II, 1861, 408.

General color grizzled gray brown, the hairs at base fulvous, subapically broadly ringed with dark brown and terminating in a long white tip; nape blackish brown; head yellowish white, from which extends posteriorly on either side a broad whitish stripe from the side of the head to the shoulder; throat, breast and limbs dark brown like the nape; rest of the lower surface paler brown varied with gray; tail like the dorsal surface, bushy-haired; ears very small, yellowish white, concealed by the surrounding pelage.

Measurements (approximate from flat skin). — Total length, 335 mm.; tail vertebræ, 65. Burmeister gives the total length as 15 inches (380 mm.)

[1] *Grison* Oken, Lehrb. der Zool., II, 1816, pp. xi and 1000. Type, *Viverra vittata* Schreber. *Cf.* Allen, Bull. Am. Mus. Nat. Hist., XVI, 1902, p. 377.

[2] *Tayra* Oken, Lehrb. der Zool., II, 1816, p. 1001. Type, *Mustela barbara* Linn. *Cf.* Allen, Bull. Am. Mus. Nat. Hist., XVI, 1902, p. 377.

and the length of the tail as 3.50 inches (89 mm.). Gervais describes the size of the animal as between that of an Ermine and a Mink.

Represented by a single imperfect flat skin, without skull or flesh measurements, obtained by Mr. Hatcher on the Rio Santa Cruz in the spring of 1899.

The species was first characterized by Gervais, in 1849, from a single skull obtained by D'Orbigny on the Rio Negro, which heretofore seems to have formed the most southern known limit of its range. Later its external characters were made known by Burmeister, from two specimens, one of which came from Azul, Argentina, near the northern boundary of Patagonia, and the other from the Rio Negro. It is said to have the savage ferocity characteristic of all the weasel tribe, and, according to Burmeister, is sometimes kept in the houses of the ranchmen to destroy rats.

Genus LUTRA Brisson.

Lutra Brisson, Règ. Anim., ed. 2, 1762, 13, 201.—Erxleben, Syst. Reg. Anim., 1777, 445.—Merriam, Science, N. S., I, No. 14, 376, April 5, 1895; type fixed as *Mustela lutra* Linn.

Two species of Otter are said to be found along the southern coast of Patagonia and in the Straits of Magellan region, namely, *Lutra felina* (Molina) and *L. paranensis* Rengger. No specimens, however, were secured by the Princeton University Patagonian Expeditions, and no Patagonian specimens are at present available for examination. Both species are fairly well known, having been repeatedly described, and their skulls at least figured.

LUTRA FELINA (Molina).

Mustela felina Molina, Sagg. Stor. Nat. Chile, 1782, 342; Comp. Hist. Geogr. Nat. y Civil de Chile, 1788, 320.

Lutra felina Shaw, Gen. Zoöl., I, pt. 11, 1800, 448.—Thomas, P. Z. S., 1881, 3 (Straits of Magellan, in part only); *ibid.*, 1889, 198 (critical).

Nutria felina Gray, P. Z. S., 1865, 128; Cat. Carniv. Br. Mus., 1869, 106.

Mustela (*Lutra*) *chilensis* Kerr, An. King., 1792, 172 (= *Lutra felina* Mol.).

Lutra chilensis Bennett, P. Z. S., 1832, 1.—Waterhouse, Zoöl. Voy. Beagle, Mamm., 1839, 23, Chonos Archipelago.—Wagner, Suppl. Schreber's Säug., II, 1842, 260.—Cunningham, Nat. Hist. Strait Magellan, 1871, 344, 350, 482.—Milne-Edwards, Miss. scient. du

Cap Horn, VI, Mamm., 1890, 14, description of animal and distribution.—Dabbene, An. Mus. nac. de Buenos Aires (3), I, 1902, 349, distribution.

Lutra californica Gray, Charlesworth's Mag. Nat. Hist., I, Nov., 1837, 580; List Mamm. Br. Mus., 1843, 71. Locality, "California," probably = Patagonia (*cf.* Thomas, P. Z. S., 1889, p. 198).

Lutra peruviensis Gervais, Voy. la Bonite, Zool., I, 1841, 15, Atlas, pl. iii, figs. 4–6, skull. "San Lorenzo du Pirou."

Lutra brachydactyla Wagner, Suppl. Schreber's Säug., II, 1842, 261, footnote. Provisional name for a specimen "aus West-Amerika."

The above citations refer to the small otter common off the coast of Chili and southward to the Straits of Magellan and the Tierra del Fuego Archipelago. During the voyage of the *Beagle* Darwin met with it in abundance and has left us the best account we have of its habits. He says:

"These animals are exceedingly common amongst the innumerable channels and bays, which form the Chonos Archipelago. They may generally be seen quietly swimming, with their heads just out of water, amidst the great entangled beds of kelp, which abound on this coast. They burrow in the ground, within the forest, just above the rocky shore, and I was told, that they sometimes roam about the woods. This otter does not, by any means, live exclusively on fish. One was shot whilst running to its hole with a large volute-shell in its mouth; another (I believe the same species) was seen in Tierra del Fuego devouring a cuttle fish. But in the Chonos Archipelago, perhaps the chief food of this animal, as well as of the immense herds of great seals, and flocks of terns and cormorants, is a red colored crab (belonging to the family Macrouri) of the size of a prawn, which swims near the surface in such dense bodies, that the water appears of a red color. This specimen weighed nine pounds and a half." (Darwin, Zoöl. Voy. Beagle, Mamm., p. 24.)

Milne-Edwards (*l. c.*, pp. 14, 15) speaks of them as very abundant in the region of Magellan Straits. He states that the officers of the *Romanch* observed them in Orange Bay, at Grévy Island, Banner Cove, and Staaten Land, and specimens were taken in Sea Gull Bay, north of Wollaston. Their skins are commonly used by the Fuegians for clothing, and a short account is given of their manner of hunting the otters.

Mr. Hatcher, in his "Narrative" (p. 247), in his account of the Channel Indians, refers to them incidentally as being hunted by these Indians, from the skins of which and of fur seals they make their scanty clothing. Mr. Barnum Brown met with them along the southern shore of Tierra del Fuego, and has kindly furnished the following from his MSS. Notes:

"Otters are numerous on the islands south of Tierra del Fuego and in Beagle and Darwin Channels. The Channel Indians spear them and sell their pelts to traders for a mere pittance. One canoe stopped our schooner and an Indian brought on board seven pelts which the captain secured for a gallon of aguardiente and a small bag of ship's biscuit."

Lutra paranensis Rengger.

Lutra paranensis Rengger, Naturg. Saeug. von Paraguay, 1830, 128–138. Paraguay. — Wagner, Suppl. Schreber's Säug., II, 1842, 261 (based on Rengger). — Burmeister, Reise durch La Plata Staaten, II, 1861, 410; Descrip. phys. Répub. Argen., III, 1879, 166. — Nehring, Sitzungsb. Ges. naturf. Freunde Berlin, 1886, 146. Rio Grande do Sul. — Thomas, P. Z. S., 1889, 199, in text, and footnote to p. 198. Straits of Magellan.

Lutra platensis Waterhouse, Zoöl. Voy. Beagle, Mamm., 1839, 21, pl. xxxv, figs. 4*a*–4*c*, skull. — Wagner, Suppl. Schreber's Säug., II, 1842, 262 (ex Waterhouse). — Thomas, P. Z. S., 1889, 199, in text.

? Lutra solitaria Wagner, Arch. f. Naturg., 1842, i, 358. Ypenema, Brazil. — Thomas, P. Z. S., 1889, 199, in text.

Lutra felina Thomas, P. Z. S., 1881, 3 (in part only; *cf. ibid.*, 1889, 198, footnote).

Lutra paraguensis Gray, P. Z. S., 1865, 128; Cat. Carniv. Brit. Mus., 1869, 107 (in error for *L. paranensis* Rengger).

Lutra latifrons Nehring, Sitzungsb. Ges. naturf. Freunde Berlin, 1887, 23, in text; in part only.

Lutra paranensis was described in 1830 by Rengger from Paraguay, who refers to it as common along the larger rivers, as the Parana and Paraguay. Waterhouse, in the "Zoölogy of the Voyage of the Beagle" (*l. c.*), redescribed it as *Lutra platensis*, from a specimen killed near Maldonado, near the mouth of the estuary of the La Plata. Burmeister, in his "Description physique de la République Argentine" (III, p. 167), says it is common along the banks of the Rio Parana, Rio Dulce, and Rio

Salado, as well as in the lakes that border them; and is also found further south along the rivers of the Provinces of Buenos Aires and the Banda Orientale, sometimes as far as the mouths of the rivers, near where they enter the ocean. The only record I know for its occurrence in the Straits of Magellan is that by Thomas (P. Z. S., 1889, p. 198, footnote, and p. 199, in text), who states that one of Dr. Coppinger's specimens taken in the Straits of Magellan, and first referred to *L. felina*, proved on a later examination of the skull to be really *L. paranensis*. Its range thus meets that of *L. felina*, and hence occurs on the coast and in the rivers of Southern Patagonia.

Family *CANIDÆ*.

The South American Canids are more or less unlike typical representatives of either *Canis*[1] (*C. lupus* group = *Lupus* Frisch, 1775) or *Vulpes*, and various names have been proposed for their generic or subgeneric designation. For the twenty species and subspecies which seem more or less well entitled to recognition at least five generic or subgeneric names (excluding synonyms) have been proposed. Of these *Speothos* Lund (1839 = *Icticyon* Lund, 1843, *apud* Thomas) is widely different from any other member of the family, and was formerly referred by some authors to the Mustelidæ; it includes the "Bush Dog" (*S. venaticus*) of Brazil, and one or more extinct cave forms from the same region.

Another very distinct group is that to which Matthew and Wortman intended to apply the name *Nothocyon*, but which, through the peculiar circumstances attending the original publication of the name, is not available in this connection. The type of *Nothocyon*[2] was intended to be

[1] By the process of elimination *Canis* Linn., 1758, is restricted to *C. familiaris*, the first of the seven species given by Linnæus under *Canis*. These species are:

1. *familiaris*, type of *Canis*, s. s., Ham. Smith, 1840; Gray, 1868.
2. *lupus*, type of *Lupus* Frisch, 1775; also of Oken, 1816, Gray, 1868, etc.
3. *hyæna*, type of *Hyæna* Brisson, 1762.
4. *vulpes*, type of *Vulpes* Frisch, 1775, and of several later authors.
5. *alopex*, = *C. vulpes* Linn.
6. *lagopus*, type of *Alopex* Kaup, 1829, and of *Leucocyon* Gray, 1868.
7. *aureus*, type of *Thos* Oken, 1816; *Vulpicanis* Blainville, 1837; *Sacalius* Ham. Smith, 1839; *Oxygoüs* Hodgson, 1841; *? Lupulus* Gervais (ex Blainville), 1855.

[2] *Nothocyon* was first proposed by Matthew (Bull. Am. Mus. Nat. Hist., XII, pp. 20, 62, March 31, 1899) without characterization (*l. c.*, p. 20), although later in the same paper (*l. c.*, p. 62) three fossil species, previously described by Cope, from the John Day (Lower Miocene)

Canis urostictus Mivart, as Dr. Matthew informs me, but as first published it did not include this species, it covering only three previously published fossil species from the Miocene of Oregon, which were later only provisionally referred to this genus, and which prove to be, as would be expected, not congeneric with *Canis urostictus* of Brazil. In allusion to this embroilment I propose for this group, should it be deemed worthy of recognition, the name **Eunothocyon,** with *Canis sladeni* Thomas as the type.[1] Here also belongs *Canis parvidens* Mivart,[2] which, like *C. urostictus*, was described as from "Brazil," without definite locality.

The "Maned Wolf" of southern Brazil, Paraguay and northern Argentina is the type and only known representative of Hamilton Smith's "section" *Chrysocyon* (*Chrysocyon jubatus* = *Canis jubatus* Desm.).

beds of Oregon were referred to it. The genus was first described nearly three months later (June 21, 1899) in a paper by Wortman and Matthew (*op. cit.*, p. 124) as "*Nothocyon*, gen. nov.," with *Canis urostictus* Mivart, as (inferentially from the context) the type, to which genus were also referred *Canis parvidens* Mivart and also "provisionally the three John Day species [*Galecynus*] *latidens* Cope, [*G*] *lemur* Cope, and *Canis geismarianus* Cope." Hay, however, in his "Bibliography and Catalogue of the Fossil Vertebrata of North America" (1902, p. 771), in entering this genus, says: "No type was designated, but *Canis geismarianus* may be taken." Palmer, two years later, in his "Index Generum Mammalium" (1904, p. 462), cites Hay, and says "type fixed" (*i. e.*, by Hay, as above). This, according to current rules of nomenclature and current usage, was a perfectly correct proceeding, although when the genus *Nothocyon* was defined it was founded on a skull of a living species from southern Brazil (Am. Mus. Osteol. Coll. Mamm., No. 391, from Chapada, Matto Grosso, Brazil = *Canis sladeni* Thomas, April, 1904), identified and figured as Mivart's *Canis urostictus*. Thus the real intention of the authors was inadvertently defeated by the original publication of the name without any reference being made to the intended type. The point is covered by Canon XXII of the A. O. U. Code, which is: "In no case should the name of a genus be transferred to a group containing none of the species originally included in the genus." There is also a similar provision in most other modern codes of nomenclature.

[1] As stated in the preceding footnote, the real basis of the diagnosis of *Nothocyon* was a skull from Chapada, Matto Grosso, which for this purpose was described in detail and figured, and identified as *Canis urostictus* Mivart. Three years later Thomas described (P. Z. S., 1903, II, p. 235, pl. xxvii, April 1, 1904) a small species, based on Chapada specimens, as *Canis sladeni*, of which the skull used as the basis of *Nothocyon* is unquestionabiy a topotype. The type of *Eunothocyon* is therefore *Canis sladeni* Thomas. The group will apparently include, besides *E. sladeni* (Thomas), *E. urostictus* (Mivart), *E. parvidens* (Mivart), and perhaps other small forms described and figured by Burmeister under apparently preoccupied names, as noted in the next footnote.

[2] Mivart considers, and probably correctly, that the *Canis vetulus* of Burmeister is not the *Canis vetulus* of Lund, leaving Burmeister's *C. vetulus* without a name, but which he provisionally refers to his *parvidens*, as he does also *Canis fulvicaudus* Burmeister (not Lund).

The "Antarctic Wolf," or "Falkland Island Dog," a species restricted to the Falkland Islands and apparently approaching extinction, is the only recognizable species of Hamilton Smith's "section" *Dusicyon* (emended to *Dasicyon* by most later writers who have referred to it); although named by Shaw, in 1800, as *Canis antarcticus*, it was first really made known by Waterhouse and Darwin (Zoöl. Voy. Beagle, Mamm., 1839, pp. 7–10, pl. iv, animal); its skull, described by Mivart (Mon. Canidæ, 1890, pp. 26–29, pl. viii, animal) in 1890, appears not to have been figured, and its claims to subgeneric distinction are not clear.

The "Azara Fox," the "Magellanic Dog," and their allies fall into Hamilton Smith's "section" *Cerdocyon* (= *Lycalopex* Burmeister, 1854, part), and seem at least subgenerically distinct from the foregoing and from the larger, broader-headed Canids of Guiana, Venezuela and Colombia. For the latter J. E. Gray proposed, in 1868, the genus *Thous*, which has been adopted as a subgenus by several later writers. This name, however, is untenable in this connection, having been applied exclusively by its proposer, Hamilton Smith, in 1839, to certain African and other species of Jackal (type, *Canis anthus* F. Cuv.). *Thous* of Gray includes the "Crab-eating Dog" (*Canis cancrivorus* Desm.) and its allies of northeastern South America, and in the absence of any synonym to replace *Thous* the group may be called **Carcinocyon** with *Canis thous*[1] Linn. (= *Canis cancrivorus* Desm.) as type, to comprise the *C. thous* group, *C. aquilus* Bangs, and probably other forms, including *Canis* **sclateri**[2] (nom. nov.).

The two species of Canids known certainly to occur in southern Patagonia belong to *Cerdocyon*, as recorded below. *C. magellanicus* is a well-marked species, quite distinct from any of its northern allies. The relation of *C. griseus* to the *C. azaræ* group is evidently close, but in the absence of specimens from Paraguay, the type region of *C. azaræ*, and of Uruguay specimens representing *C. entrerianus* (Burmeister), or of *C. vetulus* (Lund) from Minas Geraës, Brazil, it is impracticable to attempt to express an opinion as to their relationships. They are evidently closely allied, and may probably rank, with *C. griseus*, as only more or less well-marked subspecies of *C. azaræ*. All are apparently quite different from

[1] Mr. Oldfield Thomas has recently adopted (Ann. & Mag. Nat. Hist. (7), XII, Oct., 1903, p. 460, and footnote), the Linnæan name *Canis thous* (ex Guiana) in place of *cancrivorus* Desm., on seemingly reasonable grounds.

[2] *Canis microtis* Sclater, 1882, not *Canis microtus* Reichenbach, 1834, = *Canis velox* Say.

the much smaller and otherwise peculiar *Canis sladeni* Thomas from Chapada, Matto Grosso.

Genus CERDOCYON Ham. Smith.

Cerdocyon Ham. Smith, Jardine's Nat. Libr., IX, 1839, 259, 291. Includes *Canis azaræ* Wied, 1826 (= *Canis brasiliensis* Schinz, 1821), *Vulpes magellanicus* Gray, and two unidentifiable species.

Lycalopex Burmeister, Thiere Bras., 1854, 95, part, as a subgenus of *Canis;* includes *Canis azaræ* Wied, *C. vetulus* Lund, *C. cancrivorus* Desm., *C. magellanicus* Gray; Erläut. Faun. Bras., 1856, 24, 31; includes *C. cancrivorus* Desm., *C. vetulus* Lund, *C. fulvicaudus* Lund.

Lycalopex Gray, P. Z. S., 1868, 511, as a full genus, to include *L. vetulus* Lund, and *C. fulvicaudus* Lund. *C. cancrivorus* is removed as the type of Gray's *Thous*, gen. nov., nec Ham. Smith, 1839.

Pseudalopex Burmeister, Erläut. Faun. Bras., 1856, 24, 44, includes *Canis azaræ* (Wied), *C. griseus* Gray, *C. magellanicus* Gray.

Pseudalopex Gray, P. Z. S., 1858, 512 = *P. azaræ* (Wied), *P. griseus* (Gray), *P. magellanicus* (Gray), *P. antarcticus* (Shaw), *P. gracilis* (Burm.).

Cercodocyon was proposed by Hamilton Smith in 1839, as a "section" of his "subgenus" *Chaon*, for a group of species he called "Aguara Foxes," of which he recognized four species—(1) *Cerdocyon mesoleucus* sp. nov., (2) *Cerdocyon guaraxa*, sp. nov., (3) *Cerdocyon azaræ* (Wied), and (4) *Cerdocyon magellanicus* (Gray). The first was described from a living specimen said to have come from South America; "it forms," he says, "a kind of counterpart to *Thous mesomelas* of the Cape [of Good Hope], and might be mistaken for it." The specimen does not appear to have been preserved, and the species has not been since identified. The second species was described from one of the "original drawings of Prince John Maurice of Nassau-Siegen," and is also unidentifiable. This leaves within the genus two identifiable species, namely *Canis azaræ* Wied and *Vulpes magellanicus* Gray, both well known, and commonly recognized as congeneric.

Lycalopex, originally proposed by Burmeister as a subgenus of *Canis*, in 1854, contained *Canis azaræ* Wied and *C. vetulus* Lund, to which he also referred, in a footnote, *Canis cancrivorus* Desm. and *C. magellanicus* Gray. In 1856 he removed *Canis azaræ* and *C. magellanicus* to his new

subgenus, *Pseudalopex*, leaving in *Lycalopex*, of the species originally referred to it, *C. cancrivorus* and *C. vetulus*. To *Pseudalopex* he also referred *C. griseus* Gray, making *Pseudalopex* a pure synonym of *Cerdocyon*, as is also *Pseudalopex* of Gray, excluding *C. antarcticus*.

Gray, in 1868, still further restricted *Lycalopex* by removing from it *C. cancrivorus*, to form, as already stated, his new genus *Thous*, the name for which being preoccupied is above replaced by *Carcinocyon*. Of the four species originally included in *Lycalopex* two (*azaræ* and *magellanicus*) already belonged to *Cerdocyon*, and the removal of *cancrivorus* to *Thous* left in it *C. vetulus* of both Lund and Burmeister. If *C. vetulus* Burmeister is not the *C. vetulus* Lund,[1] as Mivart believed, but is referable to what Mivart saw fit to name *C. parvidens*, *C. vetulus* Burmeister was really nameless, and *Lycalopex* cannot thus take the place of *Eunothocyon*. On the other hand, *Lycalopex* cannot be made to replace *Thous*, when Gray, in establishing *Thous*, preserved *Lycalopex* for what he regarded as another and distinct genus, to include the *C. vetulus* and *C. fulvicaudus* of Lund.

Cerdocyon griseus (Gray).

(Plate XXIII, Skull.)

Canis griseus Gray, P. Z. S., 1836 (1837), 88, nomen nudum.

Vulpes griseus Gray, Charlesworth's Mag. Nat. Hist., I, Nov. 1837, 578. Straits of Magellan; type examined.

Canis griseus Burmeister, Erläut. Fauna Bras., 1856, 48, pl. xxv, animal, xxviii, fig. 3, xxix, fig. 4, skull. Sand Point, Straits of Magellan; Reise durch die La Plata-Staaten, II, 1861, 400; Desc. phys. Répub. Argent., III, 1879, 151, same specimen.—Prichard, Through Heart of Patagonia, 1902, 120, 258, 259 (habits and distribution).

Canis patagonicus Philippi, Arch. f. Naturg., 1866, i, 116. Straits of Magellan.

Canis azaræ Mivart, Mon. Canidæ, 1890, p. 66, pl. xvii, animal, from "type," figs. 25–27, skull, type of *Canis fulvipes* Martin (in part; only Patagonian references).—Hatcher, Narrative Princeton Univ. Patagonian Exped., I, 1903, 58, 68, 167 (habits and distribution).—Also of various other writers, in part.

[1] *Canis vetulus* Lund has been sometimes referred to *C. azaræ* Wied (= *C. brasiliensis* Schinz) and also to *C. gracilis* Burm. In either case it falls into the group *Cerdocyon* Ham. Smith.

External Characters.—General color above gray, varied with black, most strongly over the median dorsal area, where in some specimens there is a tendency to an ill-defined blackish median band. The pelage is long and heavy, and consists of long rather stiff over-hair and an abundance of soft woolly underfur. Top and sides of nose as far as the eyes, crown, nape, and outer surface of ears rufescent brown; forehead and sides of head more grayish, the hairs being conspicuously tipped with whitish; dorsal region gray, strongly varied with black and strongly suffused with rufous, beneath the surface the hair and fur being dusky for the basal third, then strongly yellowish rufous to the tips of the fur, the projecting points of the stiff over-hair broadly ringed with white and tipped with black; sides paler and grayer, with paler underfur and less black at the tips of the hairs; chin dusky; anal region fulvus; rest of lower surface dull yellowish gray with a whitish median band extending more or less regularly from the throat to the base of the tail; underfur dark gray basally, passing into pale yellowish gray apically, with a patch of darker underfur behind the fore limbs and just in front of the thighs; fore limbs light yellowish rufous on the anterior and inner surface and deep rufous on the posterior and outer surface; hind limbs pale fulvous anteriorly, deep dark rufous posteriorly; tail large and full, the underfur whitish gray at the base, gradually passing into dark sooty gray apically, the portion of the over-hair extending beyond the underfur yellowish gray tipped with black, giving a more or less blackish superficial tint throughout, with the whole tip of the tail black for nearly two inches; also a large well-defined spot of black near the base on the upper surface; ears externally dark cinnamon brown, the edges and inner surface pale fulvous.

Young.—The nursing pups in first pelage are clothed in a soft woolly coat, which over the whole dorsal area is dingy gray basally, darker subapically, and fulvous gray on the surface with scattered long dusky-tipped over-hair; the whole top of the head and limbs strongly reddish fulvous or pale rufous, the nose and the ears externally darker or dull brownish rufous, the edges and inner surface of the ears conspicuously whitish. Below the coloration is similar to that of the adults, as is, in fact, the general pattern of coloration, including the dusky chin and dusky plumbeous axillary patches. The extreme tip of the tail is also blackish.

Measurements. — Fourteen adults, of which 11 are males and 3 are females, taken by Mr. O. A. Peterson and measured by him in the flesh, give the following dimensions (in millimeters):

EXTERNAL MEASUREMENTS OF *Cerdocyon griseus*.

		" " 3 ♀♀		2582	288	123

Skull. — The skull is slender and fox-like, with the rostral portion long and narrow. In old skulls of both sexes the occipital crest is well developed across the central portion of the skull and there is a very short sagittal crest. The dental armature is rather weak and delicate. There are two well developed posterior cusps on $pm_{\frac{4}{4}}$, one on $pm_{\frac{3}{3}}$, with a slight indication of a second, and none or only a slight trace of one on $pm_{\frac{2}{2}}$. In much worn teeth these all nearly or quite disappear through wear, except the last posterior cusp of $pm_{\frac{4}{4}}$. $M^{\frac{2}{2}}$ is large, about half the size of $m^{\frac{1}{1}}$.

Seven fully adult skulls give the following measurements:

MEASUREMENTS OF SKULLS OF *Cerdocyon griseus*.

[1] Am. Mus. Nat. Hist.

The three specimens sexed as female by the collector (Mr. O. A. Peterson) are the largest of the series, and average a little older than the males, although all are fully adult. There is apparently little if any sexual difference in size.

This species is represented by 16 adult specimens, of which 11 are males, 3 females, and 2 without indication of sex; 11 were taken on the Rio Gallegos, May 18 to June 10, and 5 at Fairweather, June 30 to July 14. Besides these is a series of 6 young pups, representing two litters, taken respectively Nov. 16 and Nov. 29, on the Rio Coy. The 3 specimens taken on Nov. 29 are apparently several days younger than those taken Nov. 16, and also somewhat darker.

The adults vary considerably in color, especially in respect to the amount of black in the dorsal surface, and in the intensity of the fulvous and rufous tints on the limbs. One specimen (No. 92148, ♂, Rio Gallegos) differs from all the others in the very strong fulvous tinge of the whole dorsal pelage. The July (Cape Fairweather) specimens are in rather fresher, less worn coat than the May specimens, and have the whitish gray tips of the over-hair more conspicuous.

The color of the ventral surface is quite variable; in general there is a tendency to a narrow white median band extending from the throat to the tail, broadening on the throat and upper breast, and again on the posterior part of the abdomen, these two areas being connected by a narrower and somewhat irregular band. The amount and purity of the white on the ventral surface varies, and is sometimes wholly replaced by pale fulvous, without any very distinct median band. The plumbeous lateral patches, behind the fore limbs and in front of the thighs, also vary in distinctness, being sometimes strongly developed and again nearly obsolete.

Nursing pups, even of the same litter, show considerable variation in respect to the amount of fulvous suffusion, the dorsal area varying from dull dingy gray to rather strong fulvous gray.

The small gray foxes of Patagonia were referred by Mivart to *Canis azaræ* Wied,[1] under which name he "lumped" a large number of the smaller South American foxes. Other writers, notably Burmeister, have identified the animal from southern Patagonia with Gray's *Canis griseus*,

[1] The proper name of this species is *Canis brasiliensis* Schinz (Thierreich, I, 1821, 220), which antedates *azaræ* of Wied by five years (*cf.* Allen, Proc. Biol. Soc. Wash., XIV, 1901, 184).

which Gray's brief description very satisfactorily characterizes. Besides this, I have directly compared some of the Patagonian specimens with Gray's type (55–12–24–239)[1] in the British Museum and find there is no question of their identity with *C. griseus*.

The following field notes, by Messrs. Hatcher and Brown, give much new and interesting information respecting the habits and distribution of this attractive animal. Mr. Brown's notes have not been heretofore published; Mr. Hatcher's are from his recently published "Narrative" of the Princeton University Patagonian Expeditions. Mr. Brown says:

"Next to the guanaco the small fox, *Canis azaræ*, is most numerous of the larger mammals, ranging from the Straits of Magellan northward. I have seen them throughout Patagonia to 46° N., although they are most numerous near settlements in the southern part, where they feed on dead sheep and young lambs. Owing to their small size and lack of ferocity they never attack grown sheep.

"They burrow under the calafata and incensce bushes and live under the rocks along the rivers and sea coast, where it is not uncommon to see a litter of five or six young ones.

"The stealthiness with which they creep into a camp and attempt to satisfy their insatiable curiosity is wonderful, and however small a piece of tanned leather they may find it is packed off and chewed into small fragments. When journeying over the pampas it is necessary to cover saddle, bridle, harness and boots with canvass or put them out of reach of these prowlers.

"They are very fond of ostrich eggs, and as the shell is too hard for them to break with their teeth the method employed in breaking the shell is ingenious. An egg is pushed with the nose till it rolls down a bank, and if, in striking a rock, it breaks, the fox has a feast. I have seen several nests of eggs scattered at the foot of an incline, some broken by rolling against stones, and although I did not see the operation, it is vouched for by many different persons." (Barnum Brown, MSS. notes.)

At Cape Fairweather, says Mr. Hatcher: "The many cracks and crevices in the surface of the landslide were frequented by a host of small rodents, while the beautiful little gray fox or wild dog, *Canis azaræ*, was also plentiful here, as everywhere throughout the Patagonian plains.

[1] The type is a young female skin with the skull inside, with milk dentition. It was formerly mounted and has thus become somewhat faded by exposure to light as an exhibition specimen.

This little carnivore, while commonly called a fox, belongs more properly to the lupine or thoöid series of Canidæ than to the vulpine or alopecoid series. Not only is its structure wolf-like rather than fox-like, but its habits are also decidedly more similar to those of the wolves than of the foxes. It is both nocturnal and diurnal, not at all shy and easily approached. These animals are of an extremely playful and mischievous disposition, but without any of the cunning which, by common consent, has been ascribed to the foxes. At times their actions and deportment are not unlike those of a half-grown shepherd dog. They are extremely fond of rawhide or leather, and when by any chance articles made of either were left about camp within their reach for any length of time, such articles were sure to be found in an entirely ruined condition. This necessitated our placing everything beyond their reach when not in actual use. On one occasion I loaned my saddle and bridle and the borrower, on returning them in the evening, was not careful to place the latter in a safe place. As a consequence when I next wanted to use it, I found only the bit and buckles; the reins and headpieces, which were made of California red leather, were cut up into bits each not more than an inch in length. The damage wrought by these little animals would seem to be due to an inherent spirit for wanton and mischievous destruction rather than a search for food. It was never safe to picket a horse with a rope made of rawhide or a long tie strap made of leather, since either might be found cut to bits by these animals.

"They live in shallow burrows, among bushes and in the crevices of the rocks, where such are to be found. They seem to be chiefly scavengers, living for the most part upon the carcasses of dead sheep, guanaco, and other animals. They undoubtedly prey on smaller mammals and on the eggs and young of birds, when the latter are in season. Their fur is abundant, of a soft quality and rather light gray color over most of the body." (Hatcher, *l. c.*, pp. 68, 69.)

The following from Mr. Prichard's "Through the Heart of Patagonia" (pp. 258, 259) interestingly supplements the foregoing from Brown and Hatcher:

"To the east of the Andes, the pampa fox is to be met with practically everywhere. There are two varieties of foxes upon the pampa. The common pampa variety is a most inveterate thief, and causes endless trouble to travellers by eating all and anything that the wind may blow

down from the bushes, upon which one's belongings are generally hung by way of guarding against their depredations. If a horse is *sogaed* out with a *cabresto* of hide, the foxes will very often gnaw through the *cabresto* and set the horse free. This trick has cost the life of more than one Gaucho, who, travelling alone upon the pampa, in some district hundreds of miles away from human habitations, has been left quite helpless without his horse, unable to use his *bolas* with effect on foot, and so has starved to death.

"In my experience the range of the grey fox seems to cease at the foothills of the Cordillera, where the Magellan wolf (*Canis magellanicus*) is to be found. Of course, in making this statement I am open to correction. I can merely state that, during the time I spent at Lake Buenos Aires and Lake Argentino, I never saw a pampa fox, although evidences of their presence in the way of tracks were frequent, upon the north shore of the former lake. Yet directly one ascended the range of the hills towards the River Fenix, pampa foxes were to be seen. On the top of Mount Frias I saw a pampa fox in the snow. I never came upon the pampa fox in the forests which grow upon the slopes of the Cordillera.

"The fearlessness of the grey pampa fox is remarkable, even in districts where it is chased by the Indians and their dogs. The pelts are much used for making *capas* or fur cloaks. During the early part of January, 1901, upon the pampa outside the Cordillera, we continually came upon half-grown pampa foxes in twos and threes. Until they saw the dogs they never took to flight."

Cerdocyon magellanicus (Gray).

Canis magellanicus Gray, P. Z. S., 1836 (1837), 88, nomen nudum. — Burmeister, Desc. phys. Rép. Argent., III, 1879, 146 (in part). — Mivart, Mon. Canidæ, 1890, 52, fig. 21 (skull), pl. xiv (animal, type). — Milne-Edwards, Miss. Scient. du Cap Horn, VI, Zool., Mamm., 1890, 5. Orange Bay, Tierra del Fuego. — Prichard, Through Heart of Patagonia, 1902, 244–246 (colored plate of animal), 259, 260 (habits, distribution, measurements).

Vulpes magellanicus Gray, Charlesworth's Mag. Nat. Hist., I, Nov., 1837, 578. Fort Famine, Straits of Magellan. — Waterhouse, Zoöl. Beagle, Mamm., 1839, 10, pl. v, animal, Chile. (In part only — not the plate, which is based on a Chilian specimen.) — Cassin, U. S. Expl. Exped. (Wilkes), Mamm. and Orn., 1858, 22. Tierra del Fuego.

Cerdocyon magellanicus Ham. Smith, Jardine's Nat. Libr., IX, 1839, 266, pl. xxx. Based primarily on Gray as above.

Canis (Pseudalopex) magellanicus Burmeister, Erläut. Fauna Bras., 1856, 51, pl. xxvi, fig. 3, skull, Punta Arenas, Patagonia.

Pseudalopex magellanicus Gray, P. Z. S., 1868, 512; Cat. Carn. Mamm., 1869, 199.

Canis montanus Prichard, Through Heart of Patagonia, 1902, 260. A provisional name for a supposed red variety of *Canis magellanicus*. Not *Canis montanus* Marsh, 1871.

External Characters. — Much larger than *Cerdocyon griseus*, and much more strikingly colored. Head pale rufous, varied with gray and black-tipped hairs, the latter more abundant on the face and upper part of cheeks than elsewhere; back gray strongly varied with black, which is the prevailing tint over the median region from the shoulders to the tail; underfur fulvous gray; sides more fulvous, and less varied with black-tipped hairs, passing into strong fulvous or light rufous on the sides of the neck and lower part of sides; chin dusky; ventral surface yellowish white, passing into pure white on lower part of abdomen; ears externally deep rufous with a slight admixture of black-tipped hairs over the apical portion, internally yellowish white; fore limbs bright rufous externally, fulvous internally; thighs deep rufous red, paler rufous on the legs externally and fulvous internally; upper surface of tail strongly black on the basal fourth, and for three or four inches at the tip and for six or eight inches on the sides; middle portion pale fulvous with an abundance of black-tipped hairs; lower surface pale rufous for its whole length, except for the long black tip.

This beautiful species is represented by only a single flat skin, obtained by Mr. J. B. Hatcher in the "Southern Andes of Patagonia." *Cerdocyon magellanicus* is undoubtedly closely related to *Cerdocyon culpæus* (Molina), to which the present specimen may possibly be referable — a point impossible to establish in the absence of other material, especially from Tierra del Fuego, the type region of *C. magellanicus*. The present specimen, however, agrees exceedingly well with Mivart's colored plate of the type.

Mr. Brown's manuscript notes contain the following reference to the present species:

"A large fox, *Canis magellanicus*, is found in considerable numbers on Tierra del Fuego, and is reported from the Andes on the mainland. This

animal varies considerably in size, some skins being as large as a coyote."

Mr. Prichard had a more intimate acquaintance with this species, and has presented the following interesting observations:

"The study of the Cordillera wolf (*Canis magellanicus*) from the present point of view is exceptionally interesting. To this animal man is practically unknown, and it manifested the most utter fearlessness, when brought into contact with human beings, during our expedition. This wolf will advance within five or six yards of a man within open daylight; it will walk over him when asleep in camp. They haunted our camps about Lake Buenos Aires, lurking about all the night through and eating everything that came within their reach; then, instead of departing when daylight came, they usually remained crouching near by, and put in an appearance during breakfast-time with an absolute disregard or ignorance of probable danger from the neighbourhood of man.

"On the River Fenix one of these wolves came into Rosy Camp during the night, stole a duck and a goose, and further gnawed my rifle-slings within a few feet of where I was sleeping. We only discovered our loss at dawn, and while we were still discussing it, I perceived the animal itself lying under a bush close at hand calmly watching us. Deprived of breakfast, I had no thought of mercy, and shot her with a Mauser. She was an old female. That night her mate paid us a visit, and frightened the horses, who seem to fear the large Cordillera wolf almost as much as the puma. I was rather crippled at the time with an injury to my knee, and was sitting by the fire. I happened to look up and caught sight of the wolf standing within a few yards of me. He quietly returned my look but made no movement to run away. In a moment or two I got up and limped across to fetch my gun, the wolf watching me with interest, but without the smallest sign of apprehension. As a matter of fact, he came a few steps nearer to me, still gazing at me fixedly. He also joined the majority in a very short space of time. We could not afford to have such desperate thieves about our camp. At another place in the same neighbourhood a wolf, coming in to investigate our camp, was attacked by my big deerhound Tom. The wolf made no attempt to escape but met his foe with a fearful bite, and in the end we had to go to Tom's assistance before the wolf could be killed.

"From these instances it will be seen that the Cordillera wolf has absolutely no fear of man. The pampa fox shares this characteristic, but

possesses it in a much less prominent degree. . . ." (Prichard, *l. c.*, pp. 244, 245.)

"This is the animal locally known as the Cordillera fox. I have elsewhere touched upon its strongest characteristic of courage, and also the dread it inspires among horses. It is, of course, a much larger animal than the pampa fox, which latter can wander about among the troop without causing any disturbance. A single Cordillera wolf will attack young huemules as well as the young of the guanaco. Although found in the forest, this animal also frequents the plains at the foothills of the Cordillera. Personally I never observed it farther east than the River Fenix. In the one case that came under my observation, when sheep had been brought within its range, its depredations among them were considerable.

"The measurements which I made of three of these animals were as follows: Female killed at the River Fenix, Lake Buenos Aires, thirty-nine inches; dog-wolf killed at the same place, forty-one inches; dog-wolf killed at the Lake Argentino, forty-one inches. These measurements were taken from the teeth to the end of the tail directly after the shooting of the animals.

"When with young the Cordillera wolf, indeed I may say the Cordillera wolves, both male and female, will run growling towards man if he attempts to approach their litter. As far as could be judged from an examination of the lair of one, their bill of fare is very varied. There were the remains of many kinds of birds, as well as the bones of the young of guanaco and huemul." (Prichard, *l. c.*, p. 259.)

Family *FELIDÆ*.

According to Lahille[1] ten species of Felidæ occur as far south as the Argentine Republic, of which two are of doubtful status as Argentine species. Including the two Patagonia forms now recognized of the old *Felis concolor* group, four species of Lahille's list reach southern Patagonia.

In addition to these, the Jaguar (*Felis onca* Linn.) extends southward, according to authors, to northern Patagonia, ranging formerly to the Rio

[1] Ensayo sobre la distribución geográfica de los mamiferos en la República Argentina. Por el Doctor F. Lahille. Congr. cient. Lat. Amer., 1898, III (1899), pp. 165–206, with map. Felidæ, pp. 177–179.

Negro. Mr. Prichard, however, states[1] that it is not now found south of the Rio Colorado, although as late as about 1890, according to the same authority, specimens were killed near the Rio Negro.

The nomenclature and classification of the Felidæ are in a far from satisfactory state. Some authors, even in quite recent times, have referred nearly all of the hundred and fifty or more species and subspecies to the single genus *Felis*, with or without subgenera. According to Dr. Palmer,[2] the generic and subgeneric names proposed for subdivisions of the Linnæan genus *Felis*, for the existing species alone, number 58, excluding a number of alternative names not enumerated by him. The family Felidæ is by no means homogeneous, and may for convenience be divided into a considerable number of superspecific groups, several of which are clearly entitled to recognition as genera, while many others will rank as either genera or subgenera, according to the individual predilection of systematists. In recent years more and more attention has been given to the discrimination of local forms or subspecies, so that in many instances groups formally considered as wide-ranging species have been found to consist of a considerable number of more or less well-marked types, each restricted to rather definite areas, and each apparently the product of special climatic and other conditions of environment. In some cases they appear to have become fully segregated "species," but in many instances are believed to merge, through gradual geographic intergradation. In any case, the number of new forms believed to be entitled to recognition in nomenclature has of late enormously increased. Groups that formerly were looked upon as constituting a single species, now often have the rank, numerically at least, of a superspecific (or subgeneric) group, while assemblages of species formerly rated as subgenera seem to acquire, from the standpoint alike of convenience and exact taxonomic expression, an enhanced valuation. While the general tendency is to recognize this higher rating of superspecific groups as consistent with the finer ultimate divisions, a few eminent "splitters" exhibit an inconsistent tendency to lump genera.

The Felids of Patagonia and immediately adjacent territory (northward to include Paraguay) fall into several quite distinct superspecific groups, none of which are properly referable to the restricted genus *Felis* (type,

[1] Through the Heart of Patagonia, 1902, pp. 68, 248.

[2] Index Generum Mammalium, 1904, pp. 826–829.

Felis catus Linn.). The task of assigning to them their proper designations is by no means simple; the subjoined synonymy is an effort toward that end. In reviewing the names proposed for the numerous subdivisions of the Linnæan genus *Felis*, the number of synonyms based on a single species (at least five or six on *Felis planiceps*, and about the same number on *F. jubata*) is hardly less surprising than the frequency with which the same name has been used for widely different groups.

Severtzow, in a remarkable paper on the Felidæ, published in 1858, divided[1] the family into five genera and twenty-seven subgenera, to nearly all of which he gave new names (*l. c.*, X, pp. 385–389), regardless, in large part, of those given by previous authors. In most cases his subgenera were monotypic, and in addition to the names he adopted, he also provided alternative names for about one-fourth of them. We have hence names ready made for probably all possible contingencies. Yet a number of others were added by J. E. Gray in 1867,[2] but fortunately very few have been proposed since that date.[3]

[2] Notes on the Skulls of Cats. Proc. Zoöl. Soc. London, 1867, pp. 258–277. Fourteen genera, 5 additional sections (3 named), and 60 species.

[3] The superspecific names applicable to the American cats are principally the following:

For the Lynxes:

Genus LINX Frisch.

Felis Linn., Syst. Nat., 1758, 41, part, namely, *Felis lynx*.

Linx Frisch, Das Natur-System vierfuss. Thiere, 1775, *apud* Palmer, Index Gen. Mamm., 1904, 954. Type, *Felis lynx* Linn.

Lynx Kerr, Anim. Kingd., 1792, 41, 155, as a subgenus of *Felis*.

Lynceus Gray, London Med. Repos., XV, April 1821, 302; preoccupied for a genus of Crustacea (Müller, 1785).

Lynchus Jardine, Jardine's Nat. Library, Mamm., I, 1834, 274, part; full genus. = *Lynceus* Gray. — Severtzow, Rev. et Mag. de Zool. (2), X, 1858, 385, 390, part; full genus.

Lyncus Gray, List Spec. Mamm. Brit. Mus., 1843, xx, 46; P. Z. S., 1867, 276; Cat. Carn., Pachy., and Edent. Mamm., 1869, 37. Full genus, restricted to the true Lynxes.

Lynx Gray, P. Z. S., 1867, 276; Cat. Carn. . . . Mamm., 1869, 37. Subgenus of *Lynchus*, to contain the *L. borealis* and *L. canadensis* groups.

Cervaria Gray, *ibid.*, subgenus of *Lyncus*, to include the *L. pardinus* and *L. ruffus* groups. Name preoccupied in Lepidoptera (Walker, 1866).

Eucervaria Palmer, Science, N. S., XVII, 873, May 29, 1903. To replace *Cervaria* Gray.

The Jaguar group has received the following:

Felis Linn., 1758, part (*Felis onca*); also in part of most subsequent authors.

Genus PUMA Jardine.

Felis in part, of many authors.

Puma Jardine, Jardine's Nat. Library, II, 1834, 266. Full genus, to include *Felis concolor*, *F. yagouarondi*, *F. eyra*, *F. pajeros*, and two nominal species. Type by elimination, *Felis concolor* Linn., or more strictly, *Felis puma* Molina.

Leopardus Gray, List Spec. Mamm. Brit. Mus., 1843, xix, 40–44, part.

Panthera Severtzow, Rev. et Mag. de Zool. (2), X, Sept. 1858, 384, 390, part = *Leopardus* Gray. Also *Panthera* Fitzinger, 1869, part.

Puma Severtzow, *ibid.*, 384, 390, a subgenus of *Panthera*, to include only *Felis concolor* Linn.

Uncia Cope, Amer. Nat., XIV, Dec., 1880, 852, and subsequently (part); nearly equal to *Leo*, *Tigris*, and *Leopardus* (part) of Gray, 1843. Not *Uncia* of Gray, 1854, restricted to the Ounces of Asia (*Felis uncia* and allies), but includes it.—Lahille, Congr. cient. Lat. Amer., III, 1899, 177, ex Cope.

PUMA PUMA PATAGONICA (Merriam).

Felis concolor (*nec* Linn.), in part, of most authors prior to 1901.

Felis (*Uncia*) *puma* Lahille, Congr. cient. Lat. Amer., III, 1899, 177, part.

Leopardus Gray, List Spec. Mamm. Brit. Mus., 1843, xix, 40–44; P. Z. S., 1867, 263–265; Cat. Carn., Pachy., and Edent. Mamm., 1869, 10–13, part; type, *Felis leopardus* Schreber.

Panthera Severtzow, Rev. et Mag. de Zool. (2), X, Sept. 1858, 386, 390, part, with the subgenera (1) *Jaguarius*, (2) *Panthera*, (3) *Uncia*, ex Gray, 1854, (4) *Puma*, ex Jardine, 1834; all monotypic except *Uncia;* subgenus *Panthera* = *Panthera* Frisch, 1775; genus *Panthera* = *Leopardus* Gray. Also *Panthera* Fitzinger, 1869, part.

Jaguarius Severtzow, *ibid.*, 386, 390, subgenus of *Panthera*, for *Felis onca* Linn.

Onca Severtzow, *ibid.*, 390; alternative name for *Jaguarius*.

For the Eyra and Yaguarondi Cats:

Felis, in part, of most authors, even when *Felis* is taken in a more or less restricted sense. Not *Felis* s. str., with *Felis catus* as type.

Puma Jardine, Jardine's Nat. Library, II, 1834, 266, part.

Herpailurus Severtzow, Rev. et Mag. de Zool., X, Sept., 1858, 385, 390; for *Felis eyra* and *F. yagouarondi*.

Eyra Severtzow, *ibid.*, 391, alternative name for *Herpailurus*.

Catopuma Lahille, Congr. cient. Lat. Amer., III, 1899, 179. Not *Catopuma* Severtzow, 1858, type *Felis moormensis* Hodgs.

The synonymy of the Pumas, the Pampa cat, the Ocelots and other small American spotted cats, is given below, in the main text, these groups having representatives in southern Patagonia.

Felis concolor puma Prichard, P. Z. S., 1902, I, 273 (field notes); Through Heart of Patagonia, 1902, 44, 45 (description and text figure of animal), 242–244 (habits), 251–253 (habits and distribution).

Felis puma patagonica Merriam, Proc. Washington Acad. Sci., III, 1901, 598 (Dec. 11, 1901). East base of Andes, Patagonia, lat. 47° 30′.

"*Color.*—Upperparts ash gray, everywhere abundantly mixed with black hairs, the median dorsal region from top of head to end of tail suffused with buffy; belly buffy gray, the hairs much longer than on the back; pectoral and inguinal regions soiled whitish; throat gray; chin and lips white, the posterior part of upper lip and cheeks suffused with buff; patch at base of whiskers gray (instead of black); rest of face gray, except a buffy streak above and below the eye; backs of ear gray, with apical third and a faint basal band dusky; feet buffy gray; tail pale buffy fulvous above, ash gray below, with only the extreme tip dusky.

"*Cranial Characters.*—Skull massive, elongate; facial and frontal regions low and narrow; interorbital region narrow; nasals rather broad posteriorly and obliquely truncate; sagittal crest low, continuous to frontal shield; bullæ rather large; postpalatal notch broad; the palatal margin nearly straight; presphenoid normal. Canines large (the upper ones 14.5 mm. in diameter); crowns of premolars and carnassials long; upper molar small (as usual in the group); inner cusp (protocone) of upper carnassial very small. Compared with the skull of *F. puma* from Santiago, Chile, the following tooth differences are conspicuous: crown 2d upper premolar larger and thinner; crown of upper carnassial longer, with inner tubercle greatly reduced; upper molar small (less than half the size of this tooth in *puma*); 2d lower premolar smaller (decidedly less swollen); lower carnassial decidedly larger.

"Compared with an old male *concolor* from São Paulo, Brazil, the facial and frontal regions are very much lower; frontal flatter; bullæ smaller; presphenoid narrower; sphenoid suture distinct; postpalatal notch broader; sagittal crest present; underjaw more massive, the symphysis much longer; canines much larger; crown of second upper premolar much longer and narrower; crowns of upper and lower carnassial (particularly the lower) decidedly longer; crowns of lower premolars longer, the 2d much more swollen posteriorly.

"*Remarks.*—Compared with the skin of a head of *F. puma* from Santiago, Chile, the color of the corresponding parts in *patagonica* is lighter

and everywhere much grayer (less brownish and without fulvous cast); ears with distinct markings at base and tip; upper lip with only a trace of the dark mark below whiskers; lips and chin whiter; light band on under eyelid much broader and purer. Compared with subspecies *pearsoni* Thomas, the general color is much paler and grayer, the ear and face markings much more distinct, the tip of the tail dusky.

"*Measurements.* — (From dry skins). Total length 2015; tail vertebræ 670.

"*Cranial Measurements.* — Type specimen (♂ young adult) from base of Andes. Basal length 168; occipito-nasal length 177; zygomatic breadth 135; postpalatal length 86; interorbial breadth 36; upper carnassial 24.3." (Merriam, *l. c.*, pp. 598–600.)

Through the kindness of Dr. Merriam I am able to compare his type specimen (No. 108693, U. S. Nat. Mus.), skin and skull, with specimens of *pearsoni* from the Coy River. As shown by the skull, it is a young adult (said by Dr. Merriam to be a male), and the cranial differences between this skull and those of *pearsoni* pointed out by Dr. Merriam are sustained by further comparison with Rio Coy skulls, as the greater elevations of the frontal region and greater interorbial breadth of the Rio Coy specimens in comparison with the type skull of *patagonica*, and also the greater width and more abrupt posterior termination of the nasals. The teeth are much larger in *pearsoni*, the upper carnassial (p^4) having a length of 26.5 mm. as against 24 in *patagonica*, and they are quite different in form; while the body of p^4 in *pearsoni* is much broader, its transverse diameter at the front of the tooth is the same as in *patagonica*, owing to the much greater relative development of the deuterocone, which is also more pointed and more sharply set off from the body of the tooth. In other words, as said by Dr. Merriam (*l. c.*, p. 580), the inner tubercle or deuterocone is "largest and most distinct in a young male *Felis puma* from Santiago, Chile," while it is "nearly obsolete" in *pearsoni* from the coast region of Patagonia, "the inner side of the front part of the tooth sloping down [in *pearsoni*] to the inner root very gradually." The last cusp on p^3 is greatly reduced in *patagonica* as compared with the same feature in *pearsoni*. Also the last upper molar in *patagonica* is less than one half the size of the same tooth in *pearsoni*. There are thus very good cranial and dental characters to separate the two forms, apparently even specifically.

In color the type of *patagonica* is very much darker — more varied with black-tipped hairs on the median dorsal area — than the gray phase of *pearsoni* (in summer-coat), while *patagonica* is in much fuller (probably winter) pelage. On the other hand, *pearsoni* is much more strongly suffused with fulvous throughout, while the ventral surface is strongly yellowish instead of nearly clear white as in *patagonica*. There is little difference in the distinctness of the dusky ear-markings in the two forms. In general terms, *patagonica* is darker above than the gray phase of *pearsoni*, and lighter below, and almost wholly lacks the strong fulvous suffusion that forms so strong a feature in even the light phase of *pearsoni*. With the "red" phase of *pearsoni* the contrast is so great that no comparison is necessary, though in all probability, as shown by Mr. Hatcher's observations, there is also a "red" phase of *patagonica*.

Finally, in view of the strong differences in dentition between the *puma* group and *pearsoni*, especially through the practical suppression of the deuterocone in p^4 of *pearsoni* and its strong development in *patagonica*, I prefer for the present, or till more material is available for examination, to regard *pearsoni* as specifically distinct from both *Puma concolor* and *Puma puma*.

Mr. Hatcher describes the capture of the type specimen of *Puma puma patagonica*, and gives welcome information regarding its habits. He says:

"After some two weeks spent in the vicinity of Lake Pueyrredon, we decided to return to the coast. Messrs. Peterson and Brown, with the wagon and outfit, returned by the route by which we had come, while I parted company with them a short distance east of Lake Pueyrredon, and with pack-mule and saddle-horse started off to the south to explore the country lying between the lake and the headwaters of the Rios Belgrano and Chico. On the day previous to our separating, while ascending one of the lower benches of the bluff, that rises above the valley extending east of the lake, I observed a mountain lion that had been frightened from its place of concealment and went galloping up the bluff and across the narrow plain at the top. As the country was an open one and I was mounted on a good horse, this seemed an excellent opportunity and I was not slow in giving chase. Although the animal had several hundred yards the start of me, I rapidly gained on him, and when he reached the head of a small cañon at the opposite side of the narrow table I was not more than one hundred yards in the rear. On reaching

the point where he had disappeared over the crest of the bluff I halted for a moment to reconnoitre. I knew the inability of this animal, like all the others of his tribe, to maintain any considerable speed for a long distance, and that when once beyond my sight he would seek refuge in concealment rather than flight. Over the slopes and bottom of the shallow cañon there was a considerable growth of scattered brush. By carefully scanning the ground about these I soon discovered the object of my search lying stretched at full length upon the ground. To despatch him with a rifle ball was the work of but a moment and required neither skill nor courage. I preserved both skin and skeleton, and, much to my surprise, they have been considered by Dr. C. Hart Merriam as belonging to a new subspecies.

"Pretty nearly every traveler in Patagonia has remarked upon the naturally timid and cowardly nature of the puma. So far from a general disposition to attack man they are, as a rule, exceedingly timid, and examples are not at all uncommon where, when brought to bay, they have sought the shelter of a bush, and, without offering any real resistance, allowed the hunter to despatch them with his sheath knife, or by knocking them in the head with his bolas. Such timidity is not, however, universally characteristic of these animals, which are among the most abundant and by far the largest and most powerful of the Patagonian Carnivora. A notable exception to this rule, which came to the writer's knowledge, may be mentioned in this connection, since the facts connected with it are supported by unimpeachable authority. The case referred to is that of Señor Theodoro Arneberg, Chief Engineer in charge of the work of the Southern Division of the Argentine Boundary Commission. While engaged in his work in the vicinity of Lake Viedma in the autumn of 1898, in walking one day through a tangled mass of brush and tall grass, he came suddenly and unexpetedly upon a puma lying in concealment. The animal not only made no attempt to escape, but, instantly and without warning, attacked the intruder in the most savage manner. Springing upon him with its full force, it hurled him to the ground, although Mr. Arneberg is a large and powerful man, and the lion seizing him by the lower jaw, succeeded in breaking out several teeth and otherwise mutilating its then comparatively helpless victim, before one of his companions could rush up and despatch the thoroughly angered brute, which, after it had been killed, was found to be a very old male."—Hatcher, Narrative, pp. 196–198.

Mr. Brown's notes, like Mr. Hatcher's, relate in part to both of the Patagonian forms, and are as follows:

"What appears to be two species of lion, judging from the pelage, are found in southern Patagonia, ranging from the Andes to the coast. Both species are found along the coast, although it is generally understood by the sheep farmers that the red lion is a native of the mountains and follows the guanacos to the coast as those animals are driven to the sea board by the winter snows.

"I counted six lions one day while riding in the foot hills of the Andes in February, all of a decided ferruginous buff color. The gray species resembles our northern *Felis concolor* in pelage and is most often met along the coast.

"Neither species seems as fierce as the North American lion, probably because of the ease with which they get food. I heard of but one instance of a lion attacking a man, and that was in the mountains where the guanacos were scarce. The natives do not hesitate to ride onto a lion and kill it with a stirrup iron if a gun is not handy. I was on one hunt where this was done, and my friend said he had killed many in this way. I preferred, however, to shoot mine.

"In the broken camp along the coast where caves are numerous the lions breed in considerable numbers causing great destruction among the sheep. In riding through a paddock one morning I counted sixty little lambs lying dead on a side hill where during the night a lioness with two cubs had run through the bunch batting the lambs as a kitten plays with a ball." — Barnum Brown, MSS. notes.

Mr. Prichard's account of the Puma, which he calls *Felis concolor puma*, is quite in agreement with the statements of Hatcher and Brown. He credits the Puma with attacking man, but only in rare instances and in wild places remote from settlements. He says that in the Cordillera "they actually reconnoitred the camp," and "often stampeded our horses and left plain tracks near the camp, but in spite of this they killed no animal, not even a dog, belonging to us."

"Puma cubs," he says, "in captivity become very tame. One settler whom I met had two cubs about a year old. They were attached to their new home, and though they would follow a horse for two hundred yards or so, they invariably returned after a short distance to the shanty of their owner. Another puma cub . . . was wont to fight battles royal with the

hounds, but in the cold of winter would lie among them for warmth. All of these cubs were those of *Felis concolor puma*. So long as they were well fed they were docile, but when hungry their fierce nature reasserted itself. Mr. Cattle had finally to shoot the cub that belonged to him. Mr. Waring, however, still had his at the time of my departure. I heard these two killed a colt in the month of May." (Through Patagonia, pp. 222–244.)

"This," Mr. Prichard continues, "is the silver-gray variety of puma most commonly met with in Patagonia. The distribution of this animal extends over the entire country. It is to be found in the Cordillera as on the pampas. . . . The number of pumas in Patagonia is very great, more so than any zoölogist has yet given an idea of. During one winter two pioneers killed seventy-three near Lake Argentino. Near San Julian immense numbers are yearly destroyed, but lately, owing to the advent of settlers, they are becoming less numerous. At Bahia Camerones, on the farm of Mr. Greenshields, fourteen pumas were killed during the winter of 1900.

"A female killed near Santa Cruz measured 6 ft. 10 in., and a male killed near Lake Argentino 8 ft. 1 in.

"The puma can easily be galloped down, as it rarely runs more than 300 yards or a quarter of a mile when pursued on horseback. It invariably stands at bay with its back to a bush or a rock.

"In strong contradistinction to the habit of the *Felis onca* (jaguar), *F. c. puma*, when hunting, kills a number of animals from a flock or herd. To one only of these kills, however, does it return, and it always makes some pretense of burying the victim singled out for its meal, throwing upon the body in many cases merely a small bunch of thorns. This custom of the puma is frequently taken advantage of by the shepherds, who poison the chosen carcass. The puma, ninety times out of a hundred, makes its first meal upon the entrails of the victim or upon the thigh inside of the groin.

"The destruction wrought by pumas upon flocks of sheep is immense. One animal killed upwards of 100 head from among a single flock. One night alone its total amounted to fourteen. Another point in connection with the predatory habits of the puma is that it will travel a long distance, even as much as ten or twelve miles, after killing.

"Its method of attack, judging from an examination of its victims, appears to be to spring upon the shoulders of its quarry and to break its

neck. Cases are reported of pumas attacking horses, but no instance of this came under my notice. They generally select a stormy and tempestuous night during which to make their depredations. It is rather curious, as occasionally happens, to see a herd of cows with their calves take up the trail of a puma with a great deal of lowing and fuss, but they do not follow it for any distance. . . .

"Pumas are more often destroyed in winter, when the snow lies on the ground, and their tracks can be followed to their hiding places; otherwise they are so marvellously expert in concealing themselves that it is often impossible to find their lair." (*L. c.*, pp. 251–253.)

So far as known, the mainland of Patagonia forms the southern limit of distribution of both forms, they being unknown on Tierra del Fuego and neighboring islands. How far they range to the northward, or what their geographical relations are with the more northern forms of the Puma group, are matters at present quite unknown.

Puma pearsoni (Thomas).

(Plates XXV, Animal, gray phase; XXVI, Animal, red phase; XXVII–XXIX, Skull.)[1]

Felis concolor (*nec* Linn.) in part, of most authors prior to 1901. — Cunningham, Nat. Hist. Strait Magellan, 1871, 106, pl. facing p. 118, skull, from near Sandy Point, Patagonia.

Felis concolor pearsoni Thomas, Ann. & Mag. Nat. Hist. (7), VIII, Sept., 1901, 188. Santa Cruz, Patagonia, about 70 miles inland. — Prichard, P. Z. S., 1902, 274 (field notes); Through Heart of Patagonia, 1902, 155, 253 (account of the type specimen and colored plate of animal), 334, 335 (reprint of the original description by Oldfield Thomas).

Felis puma pearsoni Merriam, Proc. Washington Acad. Sci., III, 1891, 600 (Dec. 11, 1901). Based on Thomas, as above.

Red phase. — Am. Mus., No. 17434, ♀, Smith's Ranch, near mouth of Rio Coy, about sixty miles south of Santa Cruz, Patagonia; Barnum Brown. Total length, 2332 mm.; head and body, 1557; tail, without hairs, 775; hairs at end of tail, 50; ear from top of head in dried skin, 80.

Top of head, top of neck and shoulders ferruginous buffy, the tips of the hairs grayish and with a slight mixture of black-tipped hairs. This color extends down the median line of the back, forming a distinct dorsal

[1] *Felis pearsoni* on the plates.

band from two to several inches in width, but strongly varied with blackish tipped hairs. Sides of the body and outer sides of limbs pale buffy gray; ventral surface and inner side of the limbs white, the basal portion more or less buffy, particularly at the base on the abdomen. Tail strongly bicolor, the dark dorsal band being continued down the upper surface of the tail to the tip, the sides and lower surface of the tail being buffy white. Eyelids and an indistinct patch on the upper lip at the base of the whiskers blackish. Forehead and nose brownish gray, lighter and more whitish between the orbits. Ears buffy gray, mixed strongly with blackish at the base and tip, leaving an enclosed large grayish area over the middle portion. The dark color at the base and tip is strongest at the base of the ear and lighter and more mixed with brown at the apical border.

This specimen is evidently in winter coat, judging by the fullness and length of the pelage, the hairs of the upper surface of the body averaging from 25 to 30 mm. in length, while the white hairs of the lower part of the abdomen (inguinal region) attain a length of 70 to 80 mm.

Gray phase. — Am. Mus., No. 17433, ♀, Smith's Ranch, near mouth of Rio Coy, on the coast, about sixty miles south of Santa Cruz, Patagonia; Barnum Brown. Total length, 2285; head and body, 1470; tail without hairs, 815; hairs at end of tail, 55; ear from top of head in dried skin, 80.

General color above gray, slightly inclined to ferruginous on the top of the head and less so on the shoulders. A dark rufescent brown dorsal stripe about 2 to 3 inches in width extends from the shoulders to the base of the tail, slightly varied with black-tipped hairs. The gray of the sides becomes paler toward the lateral line and passes insensibly into pale buffy white on the ventral surface and inner surface of the limbs. Outer surface of the limbs like the sides of the body. Tail sharply bicolor, the upper third being a continuation of the dorsal band, but darker and more mixed with ferruginous. Sides and front of the face gray, slightly varied with black-tipped hairs; a blackish patch at the base of the whiskers; upper eyelid edged with blackish. Ears black at the base and tip, enclosing a large patch of gray.

This specimen is evidently in summer coat, the pelage being short, scarcely exceeding 15 mm. in length on the upper surface of the body.

A young example, in spotted coat (Am. Mus., No. 17435), also collected by Mr. Barnum Brown, differs considerably in color from the adult, as follows: General color above dull pale fulvous, darker over the

shoulders, along the median line, and on the outer surface of the fore limbs. Middle of the dorsal region, from the shoulders to the tail, striped and spotted with dark brown, three fairly distinct stripes running from just behind the shoulders nearly to the base of the tail, the median one darkest, and strongly defined over the posterior part of the back, and continued along the upper surface of the tail. Sides of the body indistinctly blotched with pale brown, the spots becoming more distinct and darker on the outer surface of the hind limbs. Ventral surface yellowish white, distinctly blotched with dark brown, especially on the inner side of the fore limbs. Top of the head darker than the nape and similar to the color on the top of the shoulders, except more mixed with grayish; a narrow black superciliary streak, and above this a small oval vertical blackish spot. Anterior canthus of the eye also blackish and a quite broad distinct black spot at the base of the whiskers. Back of the ears blackish brown, with a distinct paler median spot, not at all conspicuous, so that the outer surface of the ear is nearly uniform dusky brown. Forehead from the anterior canthus of the eye posteriorly to the termination of the black temple spot whitish, mixed with brownish medially. Cheeks and upper lip whitish. Nose grayish brown mixed with dusky. Fore and hind feet externally grayish fulvous, with indistinct dusky spots at the base of the toes on the fore feet. Tail on the sides and below pale fulvous brown, with a median dark stripe continued from the back over the basal half; the posterior third of the tail wholly dusky brown becoming nearly black towards and at the tip.

Skull. — The Pearson Puma is represented by two adult specimens one of which is a very old adult with strong sagittal and occipital crests; the other is fully adult. In the principal dimensions of the skull these specimens agree almost exactly with the measurements given by Dr. Merriam (Proc. Wash. Acad. Science, Vol. III, 1901, pp. 587, 588) of *Puma hippolestes* from Colorado. The chief difference consists in the much greater development of the teeth of the Patagonian form, especially the upper carnassial and molar, which considerably exceed those of the largest specimens of the *hippolestes* group. The principal measurements of the two Patagonian skulls are as follows, the larger measurements relating to the older of the two specimens: Basal length, 193 and 187; occipito-nasal length, 194.5 and 192; basal length of Hensel, 186 and 182; zygomatic breadth, 156 and 155; foramen magnum to plane of

back of last premolar, 113 and 112; interorbital breadth, 49 and 47.3; lower jaw, symphysis to condyle, 150 and 144; length of upper carnassial, 27 and 27. The upper molar has a transverse breadth of 8.6, with a length of 4 in one specimen and in the other it measures 11 x 5; this tooth being two to three times the size of the corresponding tooth in the North American forms of *Puma hippolestes*, etc.

Another striking feature of the dentition is the almost complete absence of the inner tubercle or deuterocone of the upper carnassial.

The dental armature is exceedingly heavy, the upper toothrow having a length of 52 mm. in one specimen and 50 in the other, exclusive of the molar. In the older specimens the canines have a transverse diameter of 16 and an antero-posterior diameter of 20.5, measured at the alveolar border. This specimen has the appearance of being a male. A very old *male* skull from Arizona, in which the sagittal crest is strongly developed, has teeth only half as massive as in the Patagonian skulls, which exceed in size any of the Colorado specimens of *hippolestes* of which measurements are given by Dr. Merriam.

In most respects these skulls agree with the skull of *Puma puma* from Santiago, Chili, described by Dr. Merriam (*l. c.*, page 597), except that it is larger, with even heavier dentition, and lacks the inner tubercle of the upper carnassial, which Dr. Merriam describes as "very large" in *P. puma*.

Color Phases.—The Pearson Puma presents two strongly marked phases of coloration, which appear to be purely individual and not due to either season or sex. The specimens from which the two phases of color are described above were both taken on the same ranch in Santa Cruz, but obviously at different seasons of the year. Mr. Hatcher informed me, in a letter dated December 28, 1901, that he "frequently saw and examined sets of from six to a dozen skins of these animals killed on the same farm and observed that in each instance there was every shade of color represented from very light brown or gray to dark tawny. This was true alike of individuals taken on the plains or along the mountains. I believe the color of the pelage due very largely to the season, while at the same time depending somewhat on the age and sex of the individual. In no way do I think it of specific importance."

This wide range of color variation of the Pumas is not restricted to those of Patagonia, but is recorded by Dr. Merriam as occurring in several of the North American forms. He says: "Most of the Cougars present

two color phases independent of season. One of these is usually redder than the other. Thus at any time of the year the animal of the Puget Sound region (*F. olympus*) may be 'red' or 'brown'—both of these terms, it must be understood, giving an exaggerated idea of the real color and of the difference between the two. On Vancouver Island, according to John Fanin, Curator of the Provincial Museum at Victoria, the brown pelage is the common one; the red pelage rather rare. On the mainland the red is more common. In the case of the Rocky Mountain species (*hippolestes*), according to Roosevelt [Scribner's Magazine, October, 1901, p. 435], the colors designated as 'red' and 'blue' are equally divided, six of each being recorded among the twelve animals killed by him in mid-winter in Colorado." (*L. c.*, p. 580, and table, p. 587.)

A wide range of color variation is probably present throughout the Puma group, to such an extent that characters based on coloration have very little importance; yet, in the present scarcity of material, authors are apt to lay more or less stress on such features. Thus Dr. Merriam describes his *Felis puma patagonica*, from the eastern base of the Andes, Patagonia, as being gray, with the black on the back of the ears nearly obsolete, while Mr. Thomas, in describing his *Felis concolor pearsoni*, based on a skin from Santa Cruz, coast of Patagonia, gives the coloration as fulvous or clay color, with the black on the back of the ears obsolete.

In the three specimens collected by Mr. Barnum Brown, described above, the black on the back of the ears is nearly obsolete in one, fairly distinct in another, and very strongly developed in the young specimen in spotted coat, all of these specimens being from the same locality. It would thus appear that the pattern of marking on the ear is also a variable feature, and in all probability subject to much seasonal variation.

Mr. Prichard (*l. c.*, p. 253) appears to believe that *Puma pearsoni* is especially distinguished from *P. patagonica* by its red color ("reddish-fawn instead of silver-gray"); but his personal knowledge of it appears to be confined to the type specimen, taken by him on the coast near Santa Cruz.

Genus ONCOIDES Severtzow.

Felis Linn., part, and in part of most authors.

Leopardus Gray, Ann. & Mag. Nat. Hist., X, Dec. 1842, 260, part; also Gray, 1843, 1867 and 1868, part, and of several subsequent authors who have employed the name.

Panthera Fitzinger, 1869, part.

Oncoides Severtzow, Rev. et Mag. de Zool. (2), X, Sept. 1858, 386; as a subgenus of *Felis*; includes *Felis pardalis* Linn., *Felis macroura* Wied (= *F. wiedi* Schinz, of earlier date), and *Felis tigrina*. Type, *Felis pardalis* Linn. Also of Trouessart, 1897, part, and of Lahille, 1899.

Pardalis Severtzow, *ibid.*, 391, alternative name for *Oncoides*.

Oncifelis Severtzow, *ibid.*, subgenus of *Felis*, to include only *Felis geoffroyi* Gervais.

Pardalina Gray, P. Z. S., 1867, 266. Type and only species, *Pardalina warwickii* Gray = *Felis geoffroyi* D'Orb. & Gerv., *apud* Sclater, P. Z. S., 1890, 796, and Elliot, P. Z. S., 1872, 203.

Pardalis Gray, P. Z. S., 1867, 270, as a subgenus of *Felis;* includes *F. pardalis* Linn., *Leopardus griseus* Gray, *Felis melanurus* Ball, and *Leopardus pictus* Gray. Type, *Felis pardalis* Linn.

Margay Gray, P. Z. S., 1867, 271; subgenus of *Felis*, to include *Felis macroura* Wied (= *F. wiedi* Schinz), *F. mitis* F. Cuv., *F. geoffroyi* Gerv., *F. colocola* Molina.

Zibethailurus Lahille, Congr. cient. Lat. Amer., III, 1899, 178; includes only *Felis pardalis* Linn; not *Zibethailurus* Severtzow, type and only species, *Felis viverrina* Bennett.

The name *Leopardus* Gray was apparently first used by him in a paper entitled "Descriptions of some new genera and fifty unrecorded species of Mammalia" (Ann. and Mag. Nat. Hist., Vol. X, Dec., 1842, pp. 255–267), in describing four new species of cats, two of which (*Leopardus griseus* and *L. pictus*) were from Central America, and two (*L. ellioti*, and *L. horsfieldi*) from India. There is nothing in this conection to indicate that the genus *Leopardus* was new, as is the case with ten other genera described in the same paper. A few months later (List Spec. Mamm. in Brit. Mus., 1843, pp. 40–44) he employed the name to cover a group of twenty-four species, the first of which was *Felis leopardus* Schreber, and this, bearing the same name as the genus, becomes, by rules widely accepted, the type of the genus *Leopardus*. In subsequent papers (mainly in 1867), he greatly restricted the genus by transferring from it nearly all of the species, except the *Felis leopardus* group, to other genera, including the four species originally associated with it in 1842, the two Central American species being transferred to a section (or subgenus) *Par-*

dalis of his restricted genus *Felis*. In the meantime, however, Severtzow proposed (in 1858) *Oncoides*, as a subgenus of his restricted genus *Felis*, for *Felis pardalis*, *F. macroura*, and *F. tigrina;* and also in the same paper (see synonymy above), *Oncifelis* for *Felis geoffroyi*, *Noctifelis* for *F. guigna*, *Lynchailurus* for *F. pajeros*, and *Herpailurus* for *F. jaguarondi* and *F. eyra*, all as subgenera of his restricted genus *Felis*. Names are thus provided for each of the several hitherto recognized minor groups of the smaller Central and South American cats, whether spotted or plain-colored. In the absence of sufficient material for a satisfactory revision of the South American cats, *Felis geoffroyi* is here placed in *Oncoides* with the other small spotted species, although it is evident that they constitute several well-marked sections or subgenera of *Oncoides*.

ONCOIDES GEOFFROYI (D'Orb. & Gerv.).

Felis geoffroyi D'Orbigny & Gervais, Bull. Soc. Philom., 1844, 40; Mag. de Zool., 1844, Mamm., pl. lvii, animal; Voy. Amér. Mérid., 1847, 21, pl. xiii (skull), pl. xiv (animal). Rio Negro, Patagonia.—Gray, P. Z. S., 1867, 272; Cat. Carn., Pach., and Edent. Mamm. Br. Mus., 1869, 23.—Sclater, P. Z. S., 1870, 796 (Paraguay).—Elliot, P. Z. S., 1872, 203; Mon. Felidæ, 1883, pl. xx.—Burmeister, Descrip. phys. Rép. Argent., III, 1879, 124.—Matschie, Sitzb. Ges. Nat. Fr. Berlin, 1894, 59.—A. Milne-Edwards, Miss. Cap Horn, Zool., Mamm., VI, 1890, 3, Santa Cruz, Patagonia.

Felis (*Oncifelis*) *geoffroyi* Severtzow, Rev. et Mag. de Zool. (2), X, 1858, 386, "la Plata, Patagonie."

Felis (*Oncoides*) *geoffroyi* Lahille, Congr. cient. Lat. Amer., III, 1899, 178.

Pardalina warwickii Gray, P. Z. S., 1867, 267, fig. 4 (skull), 405, pl. xxiv (animal); "Himalaya (*Warwick*). Probably from South America?"; Cat. Carn., Pach., and Edent. Mamm. Br. Mus., 1869, 14 (same as the last). (*Cf.* Sclater, P. Z. S., 1870, 796; Elliot, P. Z. S., 1872, 203.)

Felis pardinoides Gray, P. Z. S., 1867, 400; Cat. Carn. . . . Mamm., 1869, 27 (*cf.* Elliot, P. Z. S., 1872, 203).

Felis guigna Mivart (not Molina), The Cat, 1881, 410.

External Characters.—No. 16696, ♂ adult, Cañon de las Vacas, July 25, 1899; Barnum Brown. Ground color above pale yellowish gray

over the median dorsal region, lighter gray and less yellowish on the sides, passing into white on the ventral surface, everywhere irregularly spotted or streaked with black; sides of nose, edge of upper lip, a narrow streak below the eyes and a broader one above the eyes, cheeks and chin white or yellowish white; top of nose and front of head to posterior canthus of eyes grizzled yellowish gray and black; a narrow streak from nose to eye, small spot over the eye, three narrow streaks on sides of nose in the mystacial region, a streak beneath the eye, joining a broader streak behind the eye running along the side of the face, and another below this across the cheek and joining a broad transverse bar across the throat black; five narrow black stripes continued from top of head over the top of neck to the shoulders with an additional stripe on each side on the neck; area of the back from shoulders to tail, more or less blended, and giving a prevailing blackish tint to the whole median dorsal region; on each side of the median area the black spots are more scattered, variable in size and in outline from circular to elliptical, sometimes merging to form short stripes; on the flanks, limbs and ventral surface the spots are more scattered and larger, and on the ventral surface sharply contrast with the white ground color; palms and soles dark blackish brown; ears externally black with a broad central patch grayish white; tail with the basal two thirds heavily spotted and half-ringed with black, the apical third ringed and tipped with black, the last four or five rings completely encircling the tail.

Another specimen (J. B. Hatcher, mouth of Santa Cruz River) is practically the same in the general tone of the ground color, but the spots on the sides of the body are smaller, more uniformly circular and more numerous, and the stripes running from head to shoulders are less regular and continuous, and the middle of the dorsal region has the black spots and streaks less massed, giving the effect of much less black.

Measurements.—No. 16696, ♂, a flat skin gives the following dimensions, which are, of course, only approximate: Head and body, 800 mm.; tail vertebræ, 360; tip to tip of outstretched fore limbs, 690; ear from crown, 50. *Skull*: Total length, 108; basal length, 98; palatal length, 39; length of nasals, 26.5; breadth of nasals, anterior, 14, posterior, 5.5; zygomatic breadth, 73; mastoid breadth, 44.3; postorbital breadth, 28; greatest breadth of brain-case, 45; breadth at base of canines, 28; upper toothrow (molar-premolar series), 24; length of $p.^4$, 13.2; breadth at

deuterocone, 3.5; m.^{1}, length, 2; transverse breadth, 5.5; lower jaw, length, 69; height at condyle, 10; height at coronoid, 34; depth at m.$_{1}$, 12; length of toothrow, 23.

There is a striking similarity in size and general form between the skulls of *O. geoffroyi* and *L. pajeros crucina*, the two skulls before me representing these two species differing in general dimensions by only a few millimeters. The chief difference in general conformation consists in the greater and more abrupt expansion posteriorly of the zygomatic arches in *crucina* and the much greater width of the posterior nares. In dentition, however, the differences are marked, the dental armature being much heavier in *geoffroyi* than in *crucina;* the upper molar is more than twice as large in the former, and the upper premolars are longer and broader. In *geoffroyi* the lower molar has the posterior cusp or talon strongly developed, while in *crucina* it is practically obsolete, being represented by a barely perceptible knob on the inner posterior border of the cingulum.

O. geoffroyi has the skull relatively shorter and broader than in the *O. pardalis* group, with weaker dentition; it is, of course, a much smaller animal, with a relatively longer tail. It is, however, very much more different from the long-tailed, very small cats of the *O. wiedi* group.

Geographical Distribution. — *Felis geoffroyi* was originally made known from specimens collected by D'Orbigny on the banks of the Rio Negro, Patagonia. The specimens in the present collection show it to range southward to the Rio Gallegos, some five hundred miles to the southward of the type locality, and near the southern boundary of Patagonia, where it is apparently not uncommon. Burmeister reports it as occurring throughout the Argentine Republic, and states that he has seen it on the Paraná and Tucuma, and that it was found by Leubold at Mendoza.

General History. — Molina, in 1782, gave the name *Felis guigna* to a small spotted cat found in the forests of Chili, but his brief description is inadequate for the satisfactory determination of the species. The name, however, has been employed by some authors for the Patagonian animal, described as *Felis geoffroyi* by D'Orbigny and Gervais in 1844. Dr. J. E. Gray, in 1867, described a cat supposed to have come from the Himalayas, as *Pardalina warwickii*. It has since been identified by Dr. Sclater (*l. c.*) and Mr. D. G. Elliot (*l. c.*) with *Felis geoffroyi*, its supposed Indian origin having proved to be erroneous.

The *Felis guigna* of Philippi (Arch. f. Naturg., 1873, pp. 8–15, pll. ii and iii) from the province of Valdivia, Chili, is evidently very different from the Patagonian *Felis geoffroyi*, being much smaller and differently colored, with quite different cranial characters, and doubtless represents the true *F. guigna* of Molina.

Genus LYNCHAILURUS Severtzow.

Felis pajeros crucina Thomas, Ann. & Mag., Nat. Hist. (7), VIII, Sept., 1901, 247. Based on the Santa Cruz specimen collected by Darwin and described and figured by Waterhouse, as above cited.

EXTERNAL CHARACTERS. — No. 16695, male adult, Rio Gallagos, 20 miles from coast, August 12, 1899, collected and presented to the American Museum of Natural History by Mr. Barnum Brown. In winter pelage.

Pelage long and full. Especially characterized by a crest of elongated hairs along the middle of the dorsal area. General color above pale gray with a suffusion of fulvous beneath the surface and varied with black-tipped hairs; a distinct median stripe of elongated hairs extends from a little behind the shoulders to the base of the tail, the longest hairs forming a prominent crest along the middle dorsal region. These hairs are brownish fulvous at the base for three fourths of their length, then ringed with black, the band being well outlined as a pale fulvous median stripe varied with black. Sides of the nose whitish and a white ring encloses the eye except posteriorly; edge of the upper lip, chin and throat white, the lower throat marbled with irregular bands of dull fulvous, mostly concealed beneath the surface, but forming distinct crossbars on the extreme upper chest where they become darker and are succeeded by irregular narrow crossbars of black. Sides of the body with indistinct black fulvous stripes nearly concealed by the tips of the hairs, only the under-fur being fulvous. These stripes extend forward indistinctly to the cheeks, there being one just below the eye and another near the lower part of the cheek. Abdomen white, with large blackish spots more or less suffused with fulvous. Fore leg whitish with two broad rings of black and a third imperfect ring below strongly suffused with fulvous. Forefoot below fulvous, irregularly blotched with deeper fulvous. Hindfoot below fulvous, the soles deep fulvous, the lower part of the hind leg imperfectly ringed with blackish, suffused with fulvous. Ears gray posteriorly darkening to form a prominent black spot at the tip; along the edge of the ear fulvous white, the hairs of the front margin elongated. Tail grayish fulvous, the hairs brownish plumbeous basally, ringed near the tip with black and below fulvous with many black-tipped hairs; base of the tail below fulvous white.

Measurements from flat skin, tail slightly imperfect. Head and body, 790 mm.; tail, 270?; ear from crown, 45. Mr. Waterhouse gives the

measurements of his Santa Cruz specimen, reduced to millimeters as follows: Length from nose to root of tail, 660; length from nose to base of ear, 89; length of tail (fur included), 279; length of ear, 26.3; height of body at shoulders, 330.

Skull: (No. 16695, Rio Gallegos; Barnum Brown). Total length, 109; basal length, 98; palatal length, 40; length of nasals, 25; breadth of nasals, anterior, 14, posterior, 6; zygomatic breadth, 79; mastoid breadth, 50; postorbital breadth, 29; greatest breadth of brain case, 41; breadth at base of canines, 29; upper toothrow (molar-premolar series, first premolar lacking), 20.3; length of $p.\frac{4}{}$, 11.5; breadth at deuterocone, 5; $m.\frac{1}{}$, length, 2, breadth, 4; lower jaw, length, 69.5; height at condyle, 14; height at coronoid, 31.5; depth at $m._{\overline{1}}$, 31; length of toothrow, 22. In this skull there is no trace of $p.\frac{3}{}$ on either side, nor any indication of its former presence.

General History.—As shown by the references given above, the Pampa Cat was first described by Azara in 1801, under the vernacular name *Le Chat Pampa*. His description was the basis, in 1816, of two specific names, *brunneus* of Oken and *pajeros* of Desmarest. As it is doubtless impossible to determine which name was published first, and as the name *pajeros* has always been current and *brunneus* has almost escaped notice, the propriety of retaining the name *pajeros* as the specific name of the group is evident.

Mr. Brown informs me that this specimen was the only one he met with during his explorations in Patagonia. He states that it is very rare, being almost unknown to the residents of that country. Neither was it met by Mr. Hatcher during his three years work in Patagonia, nor is it mentioned by Prichard.

This form of the Pampa Cat was first described by Waterhouse in the "Zoölogy of the Beagle" (*l. c.*) who speaks of it as being remarkable for the length of the fur, and especially for the crest of elongated hair along the median line of the back. This crest is not mentioned in his description, nor is it shown in the colored plate. He says the animal is variable in markings and in the intensity of coloration. The specimen described by Mr. Waterhouse, became, in 1901, the type of Mr. Thomas's *Felis pajeros crucina*.

Darwin, in his notes on this species, as published by Waterhouse, says: "This animal takes its name from 'paja', the Spanish word for straw,

from its habit of frequenting reeds. It is common over the whole of the great plains, which compose the eastern side of the southern part of America. According to Azara, it extends northward as far as latitude 30°, and to the south, I have reasons to believe, from accounts I have received, that it is found near the Strait of Magellan, which would give it a range of nearly 1400 miles, in a north and south line. One of my specimens was obtained in 50° south, at Santa Cruz: it was met with in a valley, where a few thickets were growing. When disturbed, it did not run away, but drew itself up, and hissed. My other specimen was half-grown, and was killed in the end of August, at Bahia Blanca."

Order CHIROPTERA.

Family *VESPERTILIONIDÆ*.

While Bats in great variety reach Paraguay and northern Argentina, representing at least ten genera and about twenty species, only four species appear to have been authentically recorded from Patagonia south of the Rio Negro. None of these is represented by specimens in the collections made by the Princeton Patagonia Expeditions. Mr. Brown reports seeing a skin of a large bat in the possession of a ranchman, as noted below, which, from his account of it, was apparently *Histiotus velatus*. All of the bats reported from southern Patagonia belong to the family Vespertilionidæ, and to genera that reach, also, the highest latitudes attained by bats in the northern hemisphere.

Genus MYOTIS Kaup.

Myotis chiloensis (Waterhouse).

Vespertilio chiloensis Waterhouse, Zoöl. Voy. Beagle, Mamm., 1839,5, pl. iii, animal. Island of Chiloe, Chili. — Wagner, Schreber's Säug. Suppl., I, 1840, 536 (from Waterhouse); V, 1855, 753. — Dobson, Cat. Chirop., 1878, 322. — Lataste, Act. Soc. scien. du Chili, I, 1892, 79.

Myotis chiloensis Lahille, Congr. cient. Lat. Amer., III, 1899, 174.

Not *Vespertilio chiloensis* P. Gervais.

This species was described from a specimen obtained on one of the islets on the eastern side of the island of Chiloe, as stated by Darwin (in

Waterhouse, *l. c.*), who also says that he "saw one of these animals on the wing" in Tierra del Fuego. Dobson cites a specimen from Mendoza, Argentina; Lataste cites Valdivia, San Fernando, and Santiago, Chili; Lahille gives its range as southeastern Patagonia, Chili, and the southern part of his sub-andean province.

Genus HISTIOTUS Gervais.

HISTIOTUS VELATUS Gervais.

Plecotus velatus Gervais, Ann. Sci. Nat. (1), III, 1824, 446 (Curityba, Brazil). — Is. Geoffroy St.-Hilaire, Mag. de Zool., II, 1832, Cl. I, pl. ii, animal (same specimen as above). — Wagner, Schreber's Säug. Suppl., V, 1855, 717. — Pelzeln, Bras. Säug., 1883, 44, Ypanema, Brazil, Natterer.

Vespertilio velatus Temminck, Mongr. Mamm., II, 1835–41 (1838), 240, pl. ix, fig. 3 (Ypanema, Brazil, Natterer's specimen). — Lahille, Congr. cient. Lat. Amer., III, 1899, 173.

Histiotus velatus Gervais, Expéd. du Comte de Castelnau, Zool., 1855, 77, part, *cf.* Peters. — Peters, Monatsb. k. p. Akad. Wiss. Berlin, 1875 (1876), 787, pl., fig. 1, ear.

Vesperugo velatus Dobson, Cat. Chirop., 1878, 188.

Vesperus velatus Burmeister, Desc. phys. Rép. Argent., III, 1889, 101.

This big-eared bat ranges, according to Burmeister (*l. c.*), from southern Brazil to northern Patagonia, where specimens were taken by Mr. Henry Durnford on the Rio Chubut. Mr. Barnum Brown has described to me a specimen (skin) taken at Mr. H. S. Felton's estancia, about twenty miles from the mouth of the Rio Gallegos, which, from the size (spread of wings about 9 inches) and very large ears, seems referable to the present species.

Genus VESPERTILIO Linnæus.

VESPERTILIO MAGELLANICUS Philippi.

Vesperus magellanicus Philippi, Arch. f. Naturg., 1866, i, 113, Straits of Magellan. — Lahille, Congr. cient. Lat. Amer., III, 1899, 173. Southern Patagonia.

Vesperus magellanicus Peters, Monatsb. k. p. Akad. Wissen. Berlin, 1875 (1876), 790, pl., fig. 4 and 5, ear, skull, and dentition, from Philippi's specimen.

Vesperugo magellanicus Dobson, Cat. Chirop., 1878, 190. — Lataste, Act. Soc. scien. du Chili, I, 1892, 90. Straits of Magellan.

Vespertilio capucinus Philippi, Arch. f. Naturg., 1866, i, 114 = *V. magellanicus*, apud Peters, *l. c.*

The only definite locality known for this species for many years was that of the type, Straits of Magellan. In 1892, Lataste (*l. c.*) states that the missionary Doria had informed him that he had a specimen taken at Santa Cruz, Patagonia, and also records a specimen which he had himself examined, captured January 20, 1892, at the hacienda de San Ignacio de Peruchue, in the Province of Bio-Bio, Chili. The Santa Cruz record perhaps requires confirmation.

Genus LASIURUS Gray.

Lasiurus borealis bonariensis (Less. & Garn.).

Vespertilio bonariensis Lesson & Garnot, Voy. Coquille, Zool., I, 1826, 137–139, pl. ii, animal, skull, and teeth. Rio de la Plata. — Allen, Proc. Biol. Soc. Wash., XIII, 165, Oct. 1900; discussion of synonymy; *ibid.*, XIV, 184, Dec., 1901, synonymy of *V. villosissimus* E. Geoffroy.

Atalapha bonaërensis Burmeister, Desc. phys. Rép. Argent., III, 1879, 93. Paraguay, Chili, Patagonia. Emendation of *bonariensis*.

Lasiurus borealis bonariensis Thomas, Ann. & Mag. Nat. Hist. (7), VIII, Nov., 1901, 435, Paraguay; *ibid.*, IX, Apr., 1902, 238, footnote.

Vespertilio blossevillii Anonymous, Férussac's Bull. Sci. Nat. et Geol., VIII, No. 1, 1826, 95. "Hab. Monte-Video." = *V. bonariensis* Less. & Garn. — Allen, Proc. Biol. Soc. Wash., XIII, 165, Oct., 1900, as a synonym of *V. bonariensis*.

Atalapha blossevillei Gervais, Expéd. du Comte de Castelnau, Mamm., 1855, 72, 87, pl. xiv, fig. 2, skull and teeth, from the type specimen.

Burmeister states, under his *Atalapha bonaërensis* (*l. c.*), that he had received this species from Carmen, Patagonia, near the mouth of the Rio Negro — the most southern record I am able to trace for any form of *Lasiurus*.

Note on *Vespertilio villosissimus* Geoffroy.

Burmeister gives two species of *Atalapha* (= *Lasiurus*) as found in Paraguay and Argentina — one, his *Atalapha villosissima*, as occurring

in Paraguay, and avowedly based on Azara and Rengger, evidently mainly on the latter; the other, his *Atalapha bonaërensis*, as found in Argentina, and based on Argentine specimens. He says that the latter is one of the largest and handsomest species found in the Republic of Argentina, and gives its spread of wings as 14 inches, as against 10 to 11 in his *A. villosissima*. This would seem to indicate that his *bonaërensis* could not be a form of the *L. borealis* group, were it not that the "envergure" is inconsistent with the other measurements, thus implying an error.

Mr. Thomas has referred Lesson and Garnot's *bonariensis* to *L. borealis*, as *Lasiurus borealis bonariensis* (Ann. and Mag. Nat. Hist. (7), VIII, Nov., 1901, p. 436), adding: "The Red Bat was not observed by Azara, his *Chauve-souris septième*, the basis of *Vespertilio villosissimus*, Geoff., being clearly a southern representative of the Grey Bat (*Lasiurus cinereus*, P. de Beauv.)."

A few weeks later, in calling attention to the apparent identity of Lesson and Garnot's *Vespertilio bonariensis* (1820) with E. Geoffroy's *Vespertilio villosissimus* (1807), I incidentally said (Proc. Biol. Soc. Wash., XIV, p. 184, Dec. 12, 1901): "That Azara's Chauve-souris septième is not referable to the *Lasiurus cinereus* group, as stated by Mr. Thomas (Ann. and Mag. Nat. Hist. (7), Vol. VIII, Nov., 1901, p. 435), is evident from its small size, which barely equals that of an average example of *L. borealis*." A few months later Mr. Thomas returned to the subject (*ibid.*, IX, April, 1902, p. 238, footnote), as follows: "I can by no means accept Dr. Allen's recent alteration of my identification of Azara's 'Chauve-Souris septième' from the local race of *Lasiurus cinereus* to that of *L. borealis*, a determination I came to after most carefully weighing the claims of the three Paraguayan *Lasiuri* to this doubtful honour. I freely grant that the 'envergure' given by Azara (313 millim.) is a good deal below the corresponding dimension in fresh and well-stretched specimens of *L. cinereus;* but if Azara's specimens were a little dry and stiff, or immature, the discrepancy would easily be made up, while nothing will give any specimen of *L. borealis* an ear-length of 15 millim. . . . But the primary point is the coloration. With such conspicuously different and brilliantly colored bats as *L. cinereus* and *borealis* the first thing that would strike any, and especially any non-technical, observer is the hoary or whitish-washed colour of *cinereus* and the brilliant rufous of *borealis*. Now Azara says 'le poil est . . . d'un brun très-blanchâtre,' an expression perfectly appli-

cable to *cinereus*, hopelessly at variance with the coloration of either *borealis* or *ega*. The colour of the body and the size of the ear appear therefore to me to settle the question, and consequently I still consider Geoffroy's name *villosissimus* to be applicable to the local form of the 'très-blanchâtre' *Lasiurus cinereus*."

This question, in the abstract, is a small matter, and being averse to controversy, I had concluded to accept Mr. Thomas's argument and decision as final, until in compiling the synonymy for the record here given of a Lasiurine bat in Patagonia, it became necessary to examine critically the literature of the subject with a view to determining which of two supposed species of *Lasiurus* (*L. borealis* and *L. cinereus*) was the one represented.

The outcome has been quite different from what was anticipated, for instead of now referring *V. villosissimus* to the genus *Lasiurus* I believe it to be a species of *Dasypterus*, closely allied to *D. ega*, and apparently the earliest name for that group.

The reasons for this conclusion are as follows: The only authors who have described this bat appear to be Azara and Rengger,[1] neither of whom gives any account of the dental formula, and their accounts of the external characters are far from satisfactory. From them we gather: (1) That it was of about the size of *L. borealis*,[2] having an alar expanse of about 317 mm. (2) That it had a rather long, pointed ear,[3] much larger and differently shaped from the ear in *Lasiurus*. (3) The naked edges of the interfemoral membrane,[4] which do not exist in the *L. borealis* group, and are only slightly seen in the *L. cinereus* group. (4) The extreme softness, great

[1] Rengger cites under his *Vespertilio villosissimus* Geoff.: "Azara's chauve-souris septième."

[2] The measurements given by Azara are: "Longueur, 4 pouces 1 tiers (11 centimètres 2 tiers). Queue, 23 lignes (5 centimètres). Envergure, 11 pouces et demi (31 centimètres)."

Rengger's measurements: "Die Dimensionen dieser Fledermaus sind: 0, 9‴ Länge des Kopfes; 1″ 9‴ Länge des Rumpfes; 1″ 10‴ Länge des Schwanzes; 11″, 0 Flugweite." Adding together head, body and tail would give a total length of 4⅓ pouces, the same as Azara gives; while the "Flugweite" is a half inch less than Azara's "envergure," — a very close agreement.

[3] "L'oreille est comme celle du rat; elle est haute de 7 lignes (1 centimètre et demi)," Azara; "Die Ohren sind etwa zehn Linien lang und fanf Linien breit," Rengger.

[4] "C'est de la meme couleur qu' est la membrane de la queue; cette dernière est velue, excepté dans sa bordure," Azara; "Die Flügelhaut, bei ihrer Verbindung mit dem Rumpfe, die Arme und die Interkruralhaut, die letzteren mit Ausnahme des Randes, sind mit feinen kurzen Härchen besetzt," Rengger.

length, and the color of the pelage, which does not agree in any respect with that of *L. borealis*, nor very well with that of *L. cinereus*, but does agree in length and softness with the *Dasypterus ega* group.[1] (5) *Villosissimus* also differs from the species of *Lasiurus* in habits. Rengger says it lives in societies, often of many thousand individuals, in the lofts of churches, in hollow trees, and in clefts in rocks. The species of *Lasiurus* do not assemble in large companies, and inhabit woods, clinging head downward from the leaves and smaller branches of trees, and do not resort to cavities in trees or rocks, or to lofts of buildings.

Mr. Thomas has recorded both *Lasiurus borealis bonariensis* and *Dasypterus ega argentinus* from Central Paraguay; but there appears to be no record for the *L. cinereus* group from this region. Hence, apparently, the first specimens of Azara's Chauve-souris septième seen by any recent naturalist are those from Central Paraguay referred by Mr. Thomas to his *Dasypterus ega argentinus* (Ann. and Mag. Nat. Hist. (7), VIII, Sept., 1901, p. 247; *ibid.*, Nov., 1901, p. 435).[2]

[1] "Le poil est extrêmement doux, plus long que d'ordinaire, et d'une brun très-blanchâtre," Azara; "Der Pelz dieser Fledermaus is langharrig und weich anzufühlen," Rengger. Hence the appropriateness of the name *villosissimus*.

[2] DASYPTERUS VILLOSISSIMUS.

The synonymy of Azara's "Chauve-souris septième, ou Chauve-souris brun-blanchâtre," if the above hypothesis prove well-founded, will be as follows:

Chauve-souris septième, ou Chauve-souris brun-blanchâtre, Azara, Quad. du Paraguay, II, 1804, 284.

Vespertilio villosissimus E. Geoffroy, Ann. du Mus., VIII, 1807, 204. Based on Azara, as above. — Rengger, Naturg. Saeug. Parag., 1830, 83.

Atalapha villosissimus Burmeister, Desc. phys. Rép. Argent., III, 1879, 95.

Lasiurus villosissimus, Allen, Proc. Biol. Soc. Wash., XIV, Dec., 1901, 184, critical.

Lasiurus cinereus [*villosissimus*] Thomas, Ann. & Mag. Nat. Hist. (7), VIII, Nov., 1901, 435; inferentially; considered as "clearly a southern representative of the Grey Bat (*Lasiurus cinereus* P. de Beauv.)"; *ibid.* (7), IX, Apr., 1902, 238, footnote, reaffirming this opinion.

Dasypterus villosissimus Allen, as above.

Dasypterus ega argentinus Thomas, Ann. & Mag. Nat. Hist. (7), VIII, 1901, 247, 435.

POSTSCRIPT.

Since passing the first fifty pages of this Report for the press I have found that the name *Ctenomys robustus* as used by me (*antea*, pp. 38 *et seq.*) is preoccupied by a *Ctenomys robustus* Philippi (An. del Museo nac. de Chile, Zool., entr. 13, 1896, p. 11, pl. iv, fig. 2, animal, pl. v, fig. 1, skull; Province of Tarapaca, Chile, alt. 1200 m.). Although I have a reference in my bibliographical notes, made in 1901, to Philippi's species, I had quite overlooked the prior use of the name till recently reminded of the lapsus by my friend Mr. Wilfred H. Osgood, of the U. S. Biological Survey. My *Ctenomys robustus* (*nec* Philippi) may therefore be appropriately renamed **Ctenomys osgoodi.**

BIBLIOGRAPHY.

Following are the titles of most of the special works and papers referred to or cited in the foregoing pages. General works are not included, nor are the histories of voyages in which many of the Pinnipedia, and sometimes other species, are mentioned, even in some cases at much length. The more important of these are referred to *passim* in the text or cited in the tables of synonymy. The annotations following the titles have special reference to the bearing of the papers upon the mammals of Patagonia.

Abbott, C. C.

1868 On the Seals of the Falkland Islands, with Notes by P. L. Sclater (P. Z. S., 1868, pp. 189–192).

Notes on *Morunga elephantina*, *Otaria jubata*, *Otaria falklandica*, and *Stenorhynchus leptonyx*. Nomenclature, and comment thereon, by P. L. Sclater.

Albert, F.

1902 Los Pinipedos de Chile (Act. Soc. scient. du Chili, XI, 1902, pp. 215–272).

Descriptions and extended account of the 5 species, known from Chilian waters.

Allen, J. A.

1880 History | of | North American | Pinnipeds | A Monograph of the | Walruses, Sea-Lions, Sea-Bears | and | Seals | of | North America | — | by Joel Asaph Allen | Assistant in the Museum of Comparative Zoölogy at Cambridge | special Collaborator of the Survey | — | Washington | Government Printing Office | 1880 (Miscellaneous Publications — No. 12, U. S. Geological Survey of the Territories. F. V. Hayden, Geologist-in-Charge.) — 8vo, pp. i–xvi, 1–785, 60 text illustrations.

Treats of the classification, synonymy, nomenclature, and technical history of all the species of Pinnipedia (Otariidæ, pp. 187–231, and Phocidæ, pp. 412–557), including those of the southern hemisphere.

1892 A Synopsis of the Pinnipeds, or Seals and Walruses, in Relation to their Commercial History and Products. (Fur Seal Arbitration, Appendix to the Case of the United States before the Tribunal of Arbitration to Convene at Paris, etc., Vol. I, 1892, pp. 367–391).

List of the species of Otariidæ and Phocidæ, with notes on their distribution, and commercial value.

1892 Fur-Seal Hunting in the Southern Hemisphere (Ibid., pp. 393–404).

History of the principal Fur-Seal rookeries in the Southern Hemisphere.

1892 The Alaskan Fur-Seal and Pelagic Sealing (Ibid., pp. 405–410).

1901 New South American Muridæ and a new *Metachirus* (Bull. Am. Mus. Nat. Hist., XIV, 1901, pp. 405–412).

Eligmodontia morgani, sp. nov., p. 409. Also *Phyllotis* [*Eligmodontia griseoflavus*] *chacoensis* from the Chaco boreal of Paraguay, and *Phyllotis* [*Eligmodontia griseoflavus*] *cachinus* from Salta, Argentina (*cf.* Thomas, Ann. & Mag. Nat. Hist. (7), IX, April, 1902, pp. 240, 241).

Allen, J. A.

1901 The proper generic Names of the Viscacha, Chinchillas, and their Allies (Proc. Biol. Soc. Washington, XIV, pp. 181, 182, Dec. 12, 1901).

Viscaccia Schinz, *Chinchilla* Bennett, *Lagidium* Meyen.

1901 Note on the Names of a few South American Mammals (Proc. Biol. Soc. Washington, XIV, pp. 183–185, Dec. 12, 1901).

The specific name of the Patagonia Armadillo shown to be *ciliatus* (*Dasypus ciliatus* Fischer, 1814), and should stand as *Zaëdyus ciliatus* (Fischer).

1902 A Further Note on the Name of the Argentine Viscacha (Proc. Biol. Soc. Washington, XV, Oct. 10, 1902, 196).

The generic name *Viscaccia* Schinz, 1825, is carried back to Oken, and the specific name *chilensis* (*Lepus chilensis* Oken, 1816), is shown to have one year's priority over *maximus* (*Dipus maximus* Desmarest, ex Blainville), so that the Argentine Viscacha should stand as *Viscaccia chilensis* (Oken).

1902 The Generic and Specific Names of Some of the Otariidæ (Bull. Am. Mus. Nat. Hist., XVI, 1902, pp. 111–118).

Phoca jubata Schreber is assigned to the Northern Sea Lion, following the restriction made by Péron in 1816; *Otaria byronia* (Blainville) is shown to be the earliest available name for the Southern Sea Lion (*Otaria jubata* auct.); *Otocs* Fischer, 1817, is shown to be a pure synonym of *Otaria* Péron, 1816.

1902 Mammal names proposed by Oken in his "Lehrbuch der Zoologie" (Bull. Am. Mus. Nat. Hist., XVI, 1902, pp. 373–379).

The generic name *Viscaccia* carried back from Schinz (1825) to Oken (1816), and *chilensis* Oken (1816), shown to have priority over *maximus* Desmarest (1817) for the Viscacha of Azara.

1903 Descriptions of New Rodents from Southern Patagonia, with a note on the genus *Euneomys* Coues, and an Addendum to Article IV, on Siberian Mammals (Bull. Am. Mus. Nat. Hist., XIX, 1903, pp. 185–196).

Ctenomys robustus, C. scriceus, C. colburni, Oxymycterus microtis, Reithrodon cuniculoides obscurus, R. hatcheri, and *Euneomys petersoni,* spp. et subsp. nov.

Azara, Félix d'.

1801 Essais | sur l'Histoire naturelle | des Quadrupèdes | de la | Province du Paraguay, | Par Don Félix D'Azara, | . . . [= 5 lines, titles] | Ecrits depuis 1783 jusqu'en 1796 (an 4 de la République Française); | Avec une Appendice sur quelques Reptiles, | Et formant suite nécessaire aux Oeuvres de Buffon. | Traduits sur le Manuscrit inédit de l'Auteur, | Par M. L. E. Moreau-Saint-Méry, | . . . [= 6 lines, titles. | — | Tome Premier [Second]. | Paris, | Charles Pougens, quai Voltaire, N° 10. | — | An IX (1801). 2 vols., 8vo. Tom. I, half-title, pp. i–lxxx + 1–366; Tom. II, half-title, title page, and pp. 5–499.

An important work bearing on the mammalian fauna of Patagonia. Azara's excellent descriptions are in many instances the sole basis of names imposed by later systematists.

Lagotis pallipes sp. nov.

1835 On a New Species of *Ctenomys* Blainv. and on other Rodents collected near the Straits of Magellan by Capt. P. P. King, R.N. (P. Z. S., 1835, 189–191).

Ctenomys magellanicus, *Kerodon kingii*, *Cavia cutleri* and *Mus magellanicus* spp. nov.

Berg, C.

1898 *Lobodon carcinophagus* (H. J.) Gr. en el Rio de la Plata (Comun. Mus. Buenos Aires, I, No. 1, Aug., 1898, p. 15).

Record of two specimens taken in the Rio de la Plata, near Buenos Aires.

1898 *Dolichotis salinicola* Burm. est bona species (Comun. Mus. Buenos Aires, I, No. 1, Aug., 1898, pp. 23, 24).

Reaffirming its specific distinctness from *D. patagonica*, on the basis of an examination of specimens by Mr. Oldfield Thomas.

1898 A propósito de *Dolichotis salinicola* Burm. (Comun. Mus. Buenos Aires, I, No. 2, Dec., 1898, pp. 44, 45).

Synonymy of *D. patagonica* and *D. salinicola*.

1900–01 Notas sobre los nombres de algunos mamiferos sudamericanos (Comun. Mus. Nac. de Buenos Aires, I, No. 6, May, 1900, pp. 219–223; No. 10, Dec., 1901, pp. 260–263).

Synonymy and emendation of names: *Felis pajero*, p. 220; *Viscacia maxima*, p. 221; *Lama huanacus*, p. 260; *Mazama bisulca*, p. 262.

Blainville, H. D. de.

1820 Sur quelques Crânes de Phoques (Journ. de Physique, XCI, Oct., 1820, pp. 286–300, pl. (Dec., 1820), figs. 1–5).

Describes (p. 387) "1°. Sea Lion from the island of Tinian by Commodor Byron," which is named "*P*[*hoca*] *byronia?*" on p. 300. *P*[*hoca*] *coronata*, sp. nov. (p. 295), is based on a young mounted eared seal in Bullock's Museum, London, black, with a yellow band on the head, etc. *P*[*hoca*] *leptonyx*, sp. nov., p. 298; "*Ph. ansonina*" is proposed as a provisional name on p. 299, and repeated as "*P. ansonii*" on p. 300.

A brief review of the Seals is given (pp. 290–296), which are divided into "A. Les Phoques sans oreilles," and "B. Les Phoques à orielles." They are later grouped into five sections, A–E, on the basis of cranial characters and dentition. Altogether some 16 species are recognized.

Brooke, Sir Victor.

1878 On the Classification of the Cervidæ, with a Synopsis of the existing Species (P. Z. S., 1878, pp. 883–928, pl. lv, and 19 text figs.).

Cariacus (*Furcifer*) *antisiensis* and *C.* (*F.*) *chilensis*, pp. 923, 924, fig. 17 (antler), and *passim*.

Burmeister, Hermann.

1868 Ueber die Ohrenrobben der Ost-küste Süd-Amerikas (Zeitsch. für gesammte Naturwissenschaften Halle, XXXI, 1868, pp. 294–301).

Occurrence of *Otaria jubata* and *O. falklandica* on the coast of Buenos Aires, with critical comment on various species of authors. *Otaria ulloæ* considered to be the female of *O. jubata*, and *O. godeffroyi* believed to have been based on the male sex of *O. jubata*; *O. nigrescens* is referred to *O. falklandica*, from which *O. philippii* is thought to be perhaps separable.

1854 Systematische Uebersicht | der | Thiere Brasiliens, | welche | während einer Reise durch die Provinzen von Rio de | Janeiro und Minas geraës | gesammelt und beobachtet | wurden | von | Dr. Hermann Burmeister, | o. ö. Prof. d. Zoologie und Direct. d. zool. Mus. der Universität zu Halle. | — | Erster Theil. | Säugethiere (Mammalia). | — | Berlin, 1854. | Druck und Verlag von Georg Reimer. — 8vo, pp. x + 342.

Contains many important references to the Mammals of Patagonia.

1856 Erläuterungen | zur | Fauna Brasiliens, | enthaltend | Abbildungen und ausführliche Beschreibungen neuer | oder ungenügend bekannter Thier-Arten. | Von | Dr. Herm. Burmeister, | o. ö. Prof. d. Zoologie und Director des zoologischen Museums der Universität zu Halle. | — | Mit XXXII Tafeln. | — | Berlin. | Druck und Verlag von Georg Reimer. | 1856. — Fol., pp. i–viii + 1–115, pll. i–xxxii, part colored, of animals, part osteological.

Canidæ, pp. 1–54, pll. xvii, xxi–xxv, animals, colored, pll. xviii–xx, xxvi–xxix, skulls and dentition; Didelphiidæ, pp. 55–89, pll. i–xvi (13 colored of animals, 3 of skulls and dentition); Batrachia, pp. 90–115, pll. xxx–xxxiii.

1870 Catalogo de los Mamiferos Argentinos con las especies exoticas que se conservan en el Museo Publico de Buenos Aires (Anales del Mus. Pub. de Buenos Aires, I, 1864–1869 (1870), pp. 446–465).

References to a number of Patagonian species.

Burmeister, Hermann.

1872 Notes on *Arctocephalus hookeri*, Gray (Ann. & Mag. Nat. Hist. (4), IX, 1872, pp. 89–91).

Mainly relates to the confusion by authors, himself included, of *Arctocephalus hookeri* Gray with "*Otaria jubata* s. *leonina* of older authors," and incidentally to the characters separating the two species.

1875 Description of a new species of *Dolichotis* (P. Z. S., 1875, pp. 634–637, pl. lxix, animal).

Dolichotis salinicola, sp. nov., from the great Central Argentina Desert.

1876 Additional Notes on *Dolichotis salinicola* (P. Z. S., 1876, pp. 461, 462).

On its characters and range.

1876 Ueber einige Canis-Arten des südlichen Süd-Amerika's (Arch. f. Naturg., 1876, pt. i, pp. 116–124).

Canis gracilis Burm., in reply to Philippi, R. A., 1860, *q. v.*

1879 Description physique | de la | République Argentine | d'après des observations personelles et étrangères | par | le Dr. H. Burmeister | . . . [3 lines, titles | traduite de l'Allemand avec le concours de | E. Daireaux | . . . | Tome Troisième | Animaux Vertébrés | Première Partie | Mammifères vivants et éteints | Avec Atlas | Buénos-Ayres | Imprimerie de Paul-Émile Coni, Rue Alsina, 60 | Paris | F. Savy | Halle | Ed. Anton | En Commission | 1879 | Tous droits réservés — 8vo, pp. vi + 556.

Contains many important references to the mammals of Patagonia.

1880 Ueber *Mustela patagonica* (Arch. f. Naturg., 1880, i, 111–114).

Western Patagonia, from Mendoza southward. Its external characters and dentition.

1883 Atlas | de | la Description physique | de la | République Argentine | contenant des vues pittoresques et des figures d'histoire naturelle | composées | par | le Dr. H. Burmeister | . . . [3 lines, titles]. | Le texte traduit en Français avec le concours | de | E. Daireaux | . . . [1 line, titles] | Deuxième Section | Mammifères | — | Deuxième Livraison | Die Seehunde der Argentinischen Küsten | — | Buenos Aires | Texte de l'Imprimerie de Paul-Émile Coni, Rue Alsina, 60 | Paris | E. Deyrolle | Halle | Ed. Anton | En Commission | 1883. — Folio. [The copy examined is incomplete.]

Pl. viii, figs. 1–14 + 6*a* and 13*a*, *Otaria jubata*. Skulls of adult males and females, young male (× $\frac{2}{5}$), and a fœtal skull (× $\frac{2}{3}$); also teeth of young male and of a fœtal skull (× $\frac{1}{1}$). Pl. x, figs. 1–11 + 9*a* and 10*b*. Animal × $\frac{1}{6}$, adult ♂ skull, 3 views, × $\frac{1}{2}$; a young skull, 3 views, × $\frac{2}{3}$; teeth of adult, × $\frac{1}{1}$; osteology of fore and hind limb and hyoid, × $\frac{1}{1}$.

1888 Relacion de un Viaje a la Gobernacion del Chubut (An. Mus. Buenos Aires, III, 1888, pp. 175–252).

A list of Patagonian Mammals, pp. 239, 240.

Chapman, F. R.

1893 Notes on the Depletion of the Fur Seal in the Southern Seas (Canadian Record of Science, V, Oct., 1892, pp. 446–449).

Relates mainly to the Fur Seals of the New Zealand coasts and islands.

Cunningham, Robert O.

1871 Notes on | the Natural History | of the | Strait of Magellan | and West Coast of Patagonia | made during the Voyage of H.M.S. "Nassau" | in the years 1866, 67, 68, & 69 | By | Robert O. Cunningham, | M.D., F.L.S., etc. | Naturalist to the Expedition |

Cunningham, Robert O.

With Map and Illustrations | Edinburgh | Edmonston and Douglas | 1871 | All rights reserved — 8vo, pp. i–xviii + 1–517, map, 22 pll.

A few references to Patagonian mammals, *passim*, and illustrations of the skull of the Guanaco and Puma.

Cunningham, J. T.

1900 Sexual Dimorphism in the Animal Kingdom; a theory of the evolution of secondary sexual characters — 8vo, London, pp. xi + 317, 32 text figs.

Macrorhinus leoninus figured, pp. 67, 68.

Dabbene, A.

1902 Fauna Magallánica, — Mamíferos y Aves de la Tierra del Fuego (An. Mus. Buenos Aires (3), I, 1902, pp. 341–409).

Mammals, pp. 348–351.

Distant, W. L.

1899 The Sea Elephant (*Macrorhinus elephantinus*) (Zoölogist (4), III, Sept., 1899, pp. 385–387, pl. iii).

The plate is from a photograph of a specimen killed at the Falkland Islands. Also measurements are given in a letter, from James Smith, here reproduced, regarding the present rarity of the animal at these islands, and measurements of another (?) specimen killed at Stanley Harbor, Falkland Islands.

Elliot, D. G.

1872 On *Felis pardinoides*, J. E. Gray (P. Z. S., 1872, 203).

Felis pardinoides and *F. warwickii* Gray, both referred to *Felis geoffroyi* D'Orb.

Flower, William Henry.

1831. On the Elephant Seal, *Macrorhinus leoninus* (Linn.) (P. Z. S., 1881, pp. 145–162. with text figures).

Detailed description of skull, dentition (including milk dentition), auditory ossicles, and discussion of systematic position and affinities.

1884 Catalogue of the Specimens | illustrating the | Osteology and Dentition | of | Vertebrated Animals, | Recent and Extinct, | contained in | the Museum | of | the Royal College of Surgeons of England. | Part II. | Class Mammalia, other than Man. | By | William Henry Flower, LL.D., F. R. S., | Conservator of the Museum. | Assisted by | John George Garson, M.D., | Assistant in the Museum. | — | London: | Printed for the College; | and sold by | J. & A. Churchill, 11 New Burlington Street. | MDCCCLXXXIV. — 8vo, pp. xliii + 779.

Pinnipedia, pp. 186–218; *Otaria jubata*, pp. 187–190, including an account of the historic skull brought to England by Commodore Byron in 1769, which later formed the basis of *Phoca byronia* De Blainville, 1820; *Otaria* [= *Arctocephalus*] *australis*, p. 191; *Stenorhynchus leptonyx*, pp. 211–213; *Macrorhinus leoninus*, pp. 215–218.

Gay [Claude], et Paul Gervais.

1846 Remarques sur le *Capra pudu* et l'*Equus bisculus* de Molina (Ann. des Sci. Nat., sér. 3, Vol. V, 1846, pp. 87–94).

Cervus chilensis, sp. nov. = *Hippocamelus bisulcus* (Mol.).

Gibson, E.

1899 Field-notes on the Wood-Cat of Argentina (*Felis geoffroyi*) (P. Z. S., 1899, pp. 928, 929). Also includes measurements of two specimens.

Gray, J. E.

1837 Description of some new or little known Mammalia, principally in the British Museum Collection (Charlesworth's Mag. Nat. Hist., I, Nov., 1837, pp. 577–587).

Spp. nov.: *Vulpes magellanica*, *V. griseus*, p. 578, Straits of Magellan; *Lutra californica*, p. 580, "California" (= Patagonia?); *Conepatus* (gen. nov.) *humboldtii*, p. 581, Straits of Magellan; *Marputius* (gen. nov.), p. 581, Chili; *Leptonyx* (gen. nov.) *weddellii*, p. 582, "South Seas"; *Lepus longicaudatus*, p. 586, "Magellan Land" (= South Africa, Waterhouse).

1844–1846 Mammalia of the Zoölogy of the Voyage of the Erebus and Terror. 1844–1846. Title page not seen. See Gray, J. E., 1875.

"The Seals of the Southern Hemisphere," pp. 1–8, pll. i–x (résumé of the literature, pp. 1, 2); "Synopsis of the Species of Seals," pp. 2–5; "Description of the Seals of the Southern Hemisphere," pp. 5–8 (incomplete). *Lobodon* (p. 5) and *Ommatophoca* (p. 7), gen. nov.

Figures: *Lobodon carcinophaga*, pl. i, animal, pl. ii, skull; *Stenorhynchus leptonyx*, pl. iii, animal, pl. iv, skull; *Loptonyx weddellii*, pl. v, animal, pl. vi, skull; *Ommatophoca rossii*, pl. vii, animal, pl. viii, skull; *Morunga elephantina*, pl. ix, animal (female), pl. x, skull; *Lobodon carcinophaga*, pl. xi, skull; *Arctocephalus hookeri*, pl. xiv, animal, pl. xv, skull; *Arctocephalus lobatus*, pl. xvi, animal, pl. xvii, figs. 3–5, skull; *Otaria jubata*, juv., pl. xvii, figs. 1, 2, skull. Plates xii and xiii are lacking. Plates i–xii, 1844; pll. xiii–xvii of later date.

In the copy examined the text terminates abruptly in the middle of a sentence at the end of p. 8. It contains, however, plates ix–xvii, completing the series of seal plates, and pll. xviii–xxv of the miscellaneous mammals, pll. i–xxx of the Cetacea, and pll. i*–xxv of the birds, or the complete series of bird plates, except pll. i, vii, xii, xx*, and xxii.

See the 1875 ed., with complete text and plates.

"Sir James Ross's expedition obtained specimens of each of the four species [of Antarctic Seals], and accordingly Gray's work became, and still remains, the standard description of them all. It contains in fact the first written description of the Crab-eating Seal and of Ross's Seal, and the first intelligible description of Weddell's Seal." — Barrett-Hamilton, Report on Southern Cross Collections, 1902, p. 2.

1850 Catalogue | of the specimens of | Mammalia | in | the Collection | of the | British Museum.| Part II. | Seals. | London: | Printed by order of the Trustees.| 1850.—12mo, pp. viii + 48, text figs. 1–16.

A systematic synopsis of the Pinnipedia.

1849 On a very large Roe-Deer (*C. leucotis*) in the Collection of the Earl of Derby (P. Z. S., 1849, pp. 64, 65, pl. xii).

Capreolus leucotis, sp. nov. = *Hippocamelus bisulcus* (Mol.).

1850 Synopsis of the species of Deer (Cervina), with the description of a new species in the Gardens of the Society (P. Z. S., 1850, pp. 222–242, pl. xxii–xxviii).

Furcifer antisiensis and *F. huamel*, p. 236.

Gray, J. E.

1865 Revision of the Genera and Species of Mustelidæ contained in the British Museum (P. Z. S., 1865, pp. 100–154, pl. vii).

The species of Gray's genus *Nutria*, pp. 128, 129.

1866 Notes on the skulls of Sea Bears and Sea-Lions (Otariadæ) in the British Museum (Ann. & Mag. Nat. Hist. (3), XVIII, Sept., 1866, pp. 228–237).

Important historical and critical comment on the Falkland Island species.

1866 Catalogue | of | Seals and Whales | in the | British Museum. | By | John Edward Gray, F.R.S., V.P.Z.S., F.L.S., &c. | Second Edition. | London: | Printed by order of the Trustees. | 1866.— 8vo, pp. viii + 402, 101 text figures.

Pinnipedia, pp. 1–60, figs. 1–18.

1867 Notes on the Skulls of the Cats (Felidæ) (P. Z. S., 1867, pp. 258–277).

Systematic review of the family. *Pajeros*, gen. nov., for *Felis pajeros* Desm.

1867 Notes on certain species of Cats in the Collection of the British Museum (P. Z. S., 1867, pp. 394–405, pll. xxiv, xxv).

Contains critical comment on various South American species, with a redescription and colored plate of *Pardalina warwickii*.

1868 Observations on Sea-Bears (Otariadæ), and especially on the Fur-Seals and Hair-Seals of the Falkland Islands and Southern America (Ann. & Mag. Nat. Hist. (4), I, Feb., 1868, pp. 99–110).

Valuable historical comment on the various specimens previously received, or reputed to have come, from the Falkland Islands. Three species are recognized: (1) *Arctocephalus falklandicus*, (2) *Euotaria nigrescens*, and (3) *Phocarctos hookeri*.

1869 A New Deer from Chili (Scientific Opinion, Oct. 6, 1869, p. 385).

Anomalocera huamel, gen. et sp. nov., = *Hippocamelus bisulcus* (Mol.).

1869 On the Guemel, or Roebuck of Southern Peru (P. Z. S., 1869, pp. 496–499, text cuts of antlers and skull).

Xenelaphus huamel, gen. et sp. nov., = *Hippocamelus bisulcus* (Mol.).

1871 Supplement | to the | Catalogue | of | Seals and Whales | in the | British Museum. | By | John Edward Gray, F.R.S., F.L.S., &c. | London: | Printed by order of the Trustees. | 1871.— 8vo, pp. vi + 103, 11 text figures.

Pinnipedia, pp. 1–33. Otariidæ, 13 spp., of which five are South American.

1872 The Ears of Sea-lions and Sea-bears (Ann. & Mag. Nat. Hist. (4), IX, June, 1872, p. 483).

A short note on the size of the ears in *Otaria jubata* (= *O. byronii*) and *Arctocephalus antarcticus*, from living specimens in the London Zoölogical Gardens.

1872 On the Guémul (*Huamela leucotis*) (Ann. & Mag. Nat. Hist. (4), X, Dec., 1872, pp. 445, 446).

Genus *Huamela*, type *Capreolus leucotis* Gray; *Xenelaphus leucotis* Gray is renamed *Xenelaphus anomalocera*.

1873 Further Remarks on the Guémul of Patagonia (*Huamela leucotis*) (Ann. & Mag. Nat. Hist. (4), XI, March, 1873, pp. 214–220, fig. of skull, p. 218).

Huamela, gen. char., p. 217; characters and history of *H. leucotis* (Guémul), and *Xenelaphus anomalocera*, sp. nov.

1874 Notes on the Skulls of two undescribed Sea-lions (*Otaria*), (Ann. & Mag. Nat. Hist. (4), XIII, April, 1874, pp. 325, 326).

Gray, J. E.

Spp. nov., *Otaria minor* and *O. pygmæa*, both from unknown localities (= *Otaria byronia*).

1874 On *Xenelaphus*, *Furcifer*, and *Coassus peruvianus* (Ann. & Mag. Nat. Hist. (4), XIII, April, 1874, pp. 331, 332).

1874 Handlist of Seals, Morses, Sea-Lions, and Sea-Bears in the British Museum. London, 1874. 8vo, pp. 43, pll. i–xxx.

"Similar to the author's previous catalogues." Not seen; from Zoöl. Record, 1874.

1875[1] The | Zoology | of the | Voyage of H.M.S. Erebus & Terror, | Under the Command of Captain Sir James Clark Ross, R.N., F.R.S., | During the years | 1839 to 1843. | By Authority of the Lords Commissioners of the Admiralty. | Edited by | John Richardson, M.D., F.R.S., &c. | and | John Edward Gray, Esq., Ph.D., F.R.S., &c. | [. . .] Vol. I. | Mammalia, Birds. | [. . .] London: | E. W. Janson, 28, Museum Street, W. C. | M.DCCC.XLIV.–M.DCCC.LXXV. [4°]

VOL. I.

CONTENTS.

Chart of the South Circumpolar Region. (Frontispiece.) Title Page. Contents. Summary of the Voyage, by Joseph Dalton Hooker, M.D., F.R.S., F.L.S., &c. (pp. iii–xii). Mammalia, by J. E. Gray, Ph.D., F.R.S., F.Z.S., &c. I, The Seals of the Southern Hemisphere (pp. 1–8), *1844*, (pp. 9–12), *1875*. II, Miscellanea (pp. 12*a*–12*d*), *1875*. III, On the Cetaceous Animals (pp. 13–53), *1846*. Birds, by George Robert Gray, F.R.S., &c. (pp. 1–20), *1844–1845*. Appendix, by R. Bowdler Sharpe, F.L.S., &c. (pp. 21–39), *1875*.

PLATES.

Seals, I–X, XIV–XVII. Miscellanea, XVIII–XXII, XXV–XXIX. Cetacea, *Balæna antipodarum* (referred to at p. 16 as *B. antarctica*), I–XXXII bis, XXXIII–XXXVII. Birds, I, I *, II–XI, XI *, XIII–XX, XX *, XXI *, XXI, XXIII–XXXV. [No birds in copy examined.]

Hagmann, G.

1901 Kritische Bemerkungen zur Systematik der Amazonischen Füchse. < Zool. Anz., XXIV, 1901, pp. 509–514.

Individual variation in premolars and in other characters.

Hall, Robert.

1900 Sea-Elephants on Kerguelen's Land (Zoologist (4), IV, Oct., 1900, pp. 441–447).

Measurements, weight, habits, numbers, and method of killing them on Kerguelen Land, with cut (from a photograph) of a disturbed herd.

Hamilton, R.

1838 Observations on the Fur Seal (Ann. Nat. Hist., II, Oct., 1838, pp. 81–95, pl. iv).

General account of "the Fur Seal of commerce," named on the plate *Otaria falkandica*, and relating mainly to this species. Of much historical interest, and contains a good description of the specimens obtained by Capt. Weddell at the Falkland Islands and presented by him to the Museum of the University of Edinburgh.

[1] This work not being at hand at present, I am indebted to Dr. T. S. Palmer for the transcript, here presented, of the title page and contents. See Gray, J. E., 1844–1846, for synopsis of text and collation of plates of Pinnipedia.

Hanson, Nicolai.

1902 Extracts from the private Diary of the late Nicolai Hanson (Report Nat. Hist. Collections of the "Southern Cross," 1902, pp. 79–105), several half-tone illustrations.

Field notes, referring in part to seals, by the zoölogist of the *Southern Cross* Expedition; a half-tone cut of Ross's Seal, p. 96.

Hensel, R.

1872 Beiträge zur Kenntniss der Säugethiere Süd-Brasiliens (Abh. K. Akad. der Wissen. zu Berlin, 1872, pp. 1–130, pll. i–iii).

Includes references to a number of Patagonian species.

Heller, Edmund.

1904 Mammals of the Galapagos Archipelago, exclusive of the Cetacea (Proc. California Acad. Sci. (3), Zoöl., III, No. 7, pp. 233–250, pl. xxiii).

Otariidæ, pp. 243–248. *Arctocephalus galapagoensis*, sp. nov., p. 245.

Hudson, W. H.

1872 On the Habits of the Vizcacha (*Lagostomus trichodactylus*) (P. Z. S., 1872, pp. 822–833).

A detailed account of its habits and mode of life, based on the personal observations of the author on the pampas of Buenos Ayres.

Lahille, F.

1899 Ensayo sobre la distribución geográfica de los mamiferos de la Republica Argentina (Congr. Cien. Lat. Amer., III, 1899, pp. 165–206, with map).

Discussion of the faunal areas of Patagonia, with a map giving their boundaries, together with a list of the Mammals of Patagonia; their distribution indicated by use of the names of the faunal "provinces" here established.

Lesson, R.-P.

1826 Sur le Phoque léopard de mer (Sea Leopard) des Orcades australes; par James Weddell. (Férussac's Bull. des Sci. Nat. et de Géol., VII, 1826, 437, 438).

Otaria weddellii, sp. nov.

Lydekker, R.

1899 Specific Characters of the Chilean Guemal (P. Z. S., 1899, pp. 917–919, pl. lx), and text cut of head of adult male.

Colored plate of an adult male from Patagonia; text cut of head of a male from Ultima Esperanza, Patagonia.

Martin, William.

1837 Observations on three specimens of the genus *Felis* presented to the Society by Charles Darwin, Esq. (P. Z. S., 1837, pp. 3, 4).

Felis darwini, sp. nov., provisional name.

Matschie, P.

1894 Die von P. Neumann in Argentinien gesammelten und beobacteten Säugethiere (Sitzunsb. Ges. nat. Freunde Berlin, 1894, 56–74).

Forty-four spp. from southern Argentina and Tucuman.

Matschie, P.

1894 [Ueber *Cariacus peruvianus.*] Mittheil. Nat. Mus. Lubeck (2) (i, 1894, 129). (Not seen.)

1895 Ueber *Lyncodon patagonicum* (Sitzunsb. Ges. nat. Freunde Berlin, 1895, pp. 171–177).

1898 Hamburger Magalhænsische Sammelreise, Säugethiere. Hamburg, 1898, pp. 29, pl. 1.
Hesperomys (*Acodon*) *michaelseni*, sp. nov., p. 5, pl. i. Southern Patagonia.

Milne-Edwards, A.

1890 Mission Scientifique du Cap Horn, 1882–1883, Vol. VI, Zoologie. Mammifères, pp. 32, pll. 8.
Sixteen species, of which 8 are figured.

Merriam, C. Hart.

1897 A New Fur Seal or Sea-Bear (*Arctocephalus townsendi*) from Guadalupe Island, off Lower California (Proc. Biol. Soc. Washington, XI, 1897, pp. 175–178, July 1, 1897).
Description of the species and historical account of the known occurrence of Fur Seals at Guadalupe Island.

1901 Preliminary Revision of the Pumas (*Felis concolor* group) (Proc. Washington Acad. Sci., III, 1901, pp. 577–600).
Felis puma patagonica, subsp. nov., eastern base of Andes, Patagonia.

1902. Six new Skunks of the genus *Conepatus* (Proc. Biol. Soc. Washington, XV, pp. 161–165).
Conepatus humboldti, Patagonia, referred to incidentally, p. 165.

Mivart, St. George.

1881 The Cat. | An Introduction to the Study | of | Back-boned Animals | especially | Mammals. | By St. George Mivart, Ph.D., F.R.S. | With 200 illustrations. | London: | John Murray, Albemarle Street. | 1881. | [All Rights reserved.] — 8vo, pp. i–xxiv + 1–557, frontispiece, and 209 text-figures.
Under "Chapter XII., Different Kinds of Cats," the South American small spotted cats are treated, pp. 408–413; *Felis concolor* and *F. onca*, p. 397.

1890 Notes on the South American Canidæ (P. Z. S., 1890, pp. 98–113, figs. 1–8).
A review of the literature and of the species. Five species and 10 "varieties" recognized; *Canis parvidens* and *C. urostictus*, spp. nov.

1890 Dogs, Jackals, Wolves, and Foxes: | A | Monograph | of | the Canidæ. | By | St. George Mivart, F.R.S. | — | With woodcuts, and 45 coloured plates | drawn from nature by J. G. Keulemans and hand-coloured. | — | London: | R. H. Porter, 18 Princes Street, Cavendish Square, W., | and | Dulau & Co., 37 Soho Square, W. | 1890. — Roy. 8vo, pp. i–xxviii + 1–216, pll. col. i–xiv, text-figs. 1–59.
South American species, pp. 52–84, pll. xiv–xix, text-figs. 21–33.

Moseley, H. N.

1879 Notes by a Naturalist on the "Challenger," being an account of various observations made during the Voyage of H.M.S. "Challenger" round the World, in the years 1872–1876, under the Commands of Sir G. S. Nares, R.N., K.C.B., F.R.S., and Capt. F. T. Thompson. By H. N. Mosely, M.A., F.R.S., etc. With a Map, two coloured Plates, and numerous Woodcuts. London: Macmillan and Co. 1879. — 8vo, pp. xvi + 606.

Moseley, H. N.

Contains interesting notes on the Sea-Elephant as observed at Kerguelen Land, with copies of Anson's Sea Lion and Leseur's plate of Sea Elephants, pp. 200–206; Sea Elephant hunting and habits of Sea Elephants at Heard Island, pp. 227–229.

1892 Notes by a Naturalist. | An Account of Observations | made during | the Voyage of H.M.S. "Challenger" | round the World in the Years 1872–1876. | Under the Command of | Capt. Sir G. S. Nares, R.N., K.C.B., F.R.S., and | Capt. F. T. Thompson, R.N. | By H. N. Mosely, M.A., F.R.S., | late Fellow of Exeter College, Oxford. | A new and revised edition, with map, portrait, and woodcuts, | and a brief memoir of the Author. | New York: G. P. Putnam's Sons | London: John Murray | 1892. — 8vo, pp. xxiv + 540, with portrait, map, and numerous text-cuts.

Sea Elephants, pp. 98, 148, 174–178; Fur Seals, pp. 110, 164, 177, 179, 229, 517; Sea Leopard, p. 174. The text and illustrations are apparently the same as in the 1879 edition, *q. v.*

Müller, J.

1841 See Nilsson, 1841.

Murie, James.

1867 On the Cause of Death of the Sea-Bear (*Otaria hookeri*), lately living in the Society's Gardens (P. Z. S., 1867, pp. 243, 244).

Otaria hookeri (= *Otaria jubata* auct.) captured near Cape Horn, June, 1862.

1869 Report on the Eared Seals collected by the Society's Keeper François Lecomte in the Falkland Islands (P. Z. S., 1869, pp. 100–109, pl. vii.)

Account of external and cranial characters of *Otaria jubata*, with a colored plate of the animal, and text cuts of male and female skulls, from below, $\frac{1}{3}$ natural size, and of the "Habits and Economy of the Eared Seals."

1872 Researches upon the Anatomy of the Pinnipedia. — Parts II–III. Descriptive Anatomy of the Sea-lion (*Otaria jubata*) (Trans. Zoöl. Soc. London, VII, pt. xvi, Jan., 1872, pp. 527–596, pll. lxvii–lxxii; VIII, pt. xvi, June, 1874, pp. 501–582, pll. lxxv–lxxxii).

Detailed account of the anatomy of a specimen of *Otaria jubata* auct. from the Falkland Islands (*Cf.* Sclater, P. L., 1866, and Murie, J., 1867).

Nehring, A.

1885 Ueber das Geweih eines *Furcifer chilensis* aus Süd-Patagonien (Sitzungsb. Gesells. naturf. Freunde zu Berlin, No. 10, Dec., 1885, pp. 188–190).

Comparison of the antlers of *Furcifer chilensis* and *F. antisiensis*, with table of comparative measurements.

1886 Ueber *Furcifer antisiensis* (Sitzungsb. Gesells. naturf. Freunde zu Berlin, No. 1, Jan., 1886, pp. 17, 18).

Further comparison with *F. chilensis*.

1886 Ueber *Lutra brasiliensis*, *Lutra paranensis*, *Galictis crassidens*, und *Galera macrodon* (Sitzungsb. Gesells. naturf. Freunde zu Berlin, No. 10, Dec., 1886, pp. 144–152).

1887 Uber die Gray'schen Fischotter-Gattungen *Lutronectes*, *Lontra* und *Pteronura* (Sitzungsb. Gesells. naturf. Freunde zu Berlin, 1887, No. 3, May, 1887, pp. 20–25).

Lutra latifrons, nom. nov., for Gray's three species of *Lontra*.

1887 Ueber eine Pelzrobben Art von der Küste Süd-Brasiliens (Arch. f. Naturg., 1887, i, pp. 75–94, pl. ii), skull and dentition.

Nehring, A.

Arctocephalus (*Arctophoca*) *gracilis* sp. nov., from coast of Brazil, lat. 29° 59′ S., near mouth of Tramandahý River.

1887 Einige Notizen über die südbrasilianische Pelzrobbe (Sitzungsb. Gesells. naturf. Freunde zu Berlin, No. 8, Oct., 1887, pp. 142, 143).

Supplementary to the preceding paper.

1887 Ueber eine Pelzrobbe von Rio de Janeiro (Sitzungsb. Gesells. naturf. Freunde zu Berlin, No. 10, Dec., 1887, pp. 207, 208).

Reported capture, on the authority of Dr. Gölde, of a Fur Seal at Ponta Negra, near Rio de Janeiro, Brazil, referred by both Dr. Gölde and Dr. Nehring, to "*Arctophoca falclandica* Burmeister."

1900 Ueber *Lutra* (*Pteronura*) *paranensis* Rengger, und ein lebendes Weibchen dieser Art (Sitzungsb. Gesells. naturf. Freunde zu Berlin, No. 10, Dec., 1900, pp. 221–228).

1900 Ueber *Ctenomys pundti* n. sp., und *Ct. minutus* Nhrg. (Zool. Anz., XXIII, 1900, pp. 420–423, figs. 1, 2), top view of skulls of *Ct. pundti* and *Ct. minutus*.

1900 Ueber *Ctenomys neglectus* n. sp., *Ct. nattereri* Wagn. und *Ct. lutjanensis* Amegh. (Zool. Anz., XXIII, Oct., 1900, pp. 535–541, figs. 1–3).

Ctenomys neglectus, sp. nov. (p. 535, fig. 1, skull), based on a weathered skull from Patagonia.

1900 Ueber die Schädel von *Ctenomys minutus* Nhrg., *Ct. torquatus* Licht. und *Ct. pundti* Nhrg. (Sitzungsb. Gesells. naturf. Freunde zu Berlin, No. 9, Nov., 1900, pp. 201–210), mit 7 figs.

1901 Einige Notizen über die *Lutra* (*Pteronura*) *paranensis* des hiesigen zoologischen Gartens (Sitzungsb. Gesells. naturf. Freunde zu Berlin, No. 3, März, 1901, pp. 133–135).

Nilsson, S.

1837 Utkast till en systematisk indelning af Phocacierna (K. Vet. Akad. Handl. Stockholm, LVIII, 1837, pp. 235–240).

Not now accessible; see the German translation, Nilsson, 1841.

1841 Entwurf einer systematischen Eintheilung und speciellen Beschreibung der Phoken, von Nilsson. Aus dem Schwedischen übersetzt von Dr. W. Peters (Arch. f. Naturg. 1841, i, pp. 301–334).

An important revision of the subject with remarks (in footnotes) and a supplement by J. Müller.

Owen, Richard.

1843 Notice of a new species of Seal (*Stenorhynchus serridens*) (Ann. & Mag. Nat. Hist., XII, Nov., 1843, pp. 331, 332).

= *Lobodon carcinophaga* (Jacq. & Puch.).

Peters, W.

1866 Ueber die Ohrenrobben (Seelöwen und Seebären), *Otariæ*, inbesondere über die in den Sammlungen zu Berlin befindlichen Arten. (Monatsb. K. Akad. zu Berlin, 1866, pp. 261–281, pll. i, ii, ii*b*, ii*c*).

A general review of the group, of which 14 species, all placed in *Otaria*, are indicated, of which 3 appear to be considered doubtful. *Phocarctos* (p. 269) and *Arctophoca* (p. 276) proposed as new subgenera; *Otaria godeffroyi*, sp. nov. (p. 266, pl. i), based on an old male skull, from Chincha Islands, Peru; *Otaria philippii*, sp. nov. (p. 276, pll. ii*a*, ii*b*, ii*c*), based on a skull from Juan Fernandez Island.

Peters, W.

1866 Nachtrag zu seiner Abhandlungen über die Ohrenrobben (*Otariæ*) (Monatsb. K. Akad. zu Berlin, 1866, pp. 665–672, with plate).

Further comment, the species here apparently reduced to 10. The skull of *Otaria ulloæ* figured. A synopsis of the species (pp. 670–672), which are placed in 7 subgenera.

1871 Ueber die Verschiedenheit der in dem atlantischen und stillen Ocean vorkommenden Pelzrobben (Monatsb. K. Akad. zu Berlin, 1871, pp. 563–566).

Otaria argentata Philippi is thought to be the female of *O. philippii* Peters, and *Otaria falklandica* (Shaw) the female of *O. nigrescens* Gray; refers to the great similarity between *O. philippii* and *O. nigrescens* and raises the question of their specific distinctness.

1876 Ueber die mit *Histiotus velatus* verwandten Flederthiere aus Chile (Monatsb. K. Akad. zu Berlin, 1875 (1876), pp. 785–782, with pl.)

Vesperus (*Histiotus*) *velatus* I. Geoffroy, *Vesperus* (*H.*) *macrotus* Pöppig, and *Vesperus montanus* Philippi discussed at length; ear, head, skull, and dentition figured.

1877 Ueber die Ohrenrobben, *Otaria*, als Nachtrag zu seiner im vorigen Jahre über diese Thiere gelesenen Abhandlung. (Monatsb. K. P. Akad. Wissen. zu Berlin, 1877, pp. 505–507).

Supplement to a paper of the previous year on Eared Seals, read before the Academy June 12, 1876, but apparently not published (*cf. op. cit.*, 1876, p. 327). Systematic list of genera and species, with annotations; 3 genera, 13 species.

Philippi, R. A.

1866 Ueber ein paar neue Chilenische Säugethiere (Arch. f. Naturg., 1866, pt. i, pp. 113–117).

Vespertilio magellanicus, p. 113, Straits of Magellan; *Canis patagonicus*, p. 116, Straits of Magellan.

1870 Eine vermeintliche neue Hirschart aus Chile (Arch. f. Naturg., 1870, i, pp. 46–49).

Comment on *Anomolocera leucotis* Gray, doubting especially its alleged Chilian habitat.

1871 Ueber eine für Chile neue Art von *Otaria* (Monatsb. K. Akad. zu Berlin, 1871, pp. 558–562, pll. 2).

Otaria argentata, sp. nov. (p. 560, text, and pll. i and ii, skull), from Mas a Fuera.

1873 Ueber *Felis Guiña* Molina und über die Schädelbildung bei *Felis Pajeros* und *Felis Colocolo* (Arch. f. Naturg., 1873, i, pp. 8–15, pll. ii, iii).

Pl. iii, fig. 3 and 4, skull of *Felis pajeros*.

1892 Las Focas Chilenas del Museo Nacional (An. Mus. Nac. Chile, 1892, Zool., Ent., 1, pp. 1–52, pll. i–xxiii).

Otaria jubata, p. 9, pl. i, animal; *O. ulloæ*, p. 12, pl. vi, animal; *O. velutina*, sp. nov., p. 14, pll. vi, vii (skull), viii, animal (*O. ulloæ* on plates); *O. fulva*, sp. nov., p. 17, pll. ii, animal, iii–v, skull; *O. molossina*, p. 22, pl. ix, animal, x, skull of very young specimen; *O. chilensis*, p. 25, pll. xi, animal, xii, skull, young with milk dentition; *O. rufa*, sp. nov., p. 28, pl. xiii, animal; *O. philippii*, p. 33, pll. xiv, xv, animal, xvi–xix, skulls; *O. argentata?*, p. 38, pl. xx; *O. australis*, p. 40, pll. xi, animal, xxi, skull, young — "*O. falklandica*" on plates; *O. brachydactyla*, sp. nov., p. 43, pll. xiii, xxii, skull with milk dentition; *O. leucostoma*, sp. nov., p. 46, pl. xxiii, animal; *O. aurita*, p. 47, from

Philippi, R. A.

Tschudi. *O. chonotica*, p. 49, is a provisional name, suggested by Matschie, for *O. chilensis* Müller.

1892 El Guemel de Chile (An. Mus. Nac. Chile, 1892, pp. 1–9 with plate).

On the Taruga (*Cervus antisiensis*) and the Guemul (*C. chilensis*); chiefly historical.

1894 *Cervus antisiensis, chilensis, brachyceros* (An. Mus. Nac. Chile, Zool., Entr. 7, 1894, pp. 1–16, pll. i–iv).

Synonymy and descriptions, with figures of the animals and skulls, and critical comparison of the species. *Cervus brachyceros* evidently based on malformed antlers of *C. antisiensis*.

1896 Descripcion de los Mamíferos triados del viaje de esploracion a Tarapacá, hecho por órden del Gobierno en el Verandode, 1884 a 1885 (An. Mus. Nac. Chile, 1899, Zool., Entr. 13, pp. 1–24, pll. i–vii).

Vespertilio atacamensis (p. 5), *Lagidium lutescens* (p. 8), four species of *Ctenomys*, and five species of "*Hesperomys*" described as new, and all figured.

1900 Figuras y descripciones de los Murídeos de Chile (An. Mus. Nac. Chile, Zool., Entr. 14[a], pp. 1–70, pll. i–xxv).

A large number of species of "*Mus*" described and figured as new.

1901 Neuva especie Chilena de Zorras (An. Univ. Chile, Feb., 1901, pp. 167–170, 1 pl.).

Canis domeykoanus, sp. nov., Island of Chiloe.

1903 Einige neue Chilenische *Canis*-Art. (Arch. f. Nat., 1903, i, pp. 155–169).

Canis amblydon, C. maullinicus, C. trichodactylus, C. albigula, C. torquatus, spp. nov.!

Prichard, H. H.

1902 Field-Notes on the larger Mammals of Patagonia (P. Z. S., 1902, I, pp. 272–277).

Notes on the Huemul, Guanaco, Puma, Pearson's Puma, Patagonian Cavy, and Little Armadillo.

1902 Through the Heart | of Patagonia | By | H. Hesketh Prichard | F.R.G.S., F.Z.S. | Fellow of the Anthropological Institute; author of | "Where Black rules White: A Journey | across and about Hayti" | With illustrations from drawings in colour | and black and white by | John Guille Millais, F.Z.S. | and from photographs | New York | D. Appleton & Company | 1902 — Imp. 8vo, pp. i–xvi + 1–346, with 39 full-page colored and plain illustrations, 87 text figures, and 3 maps. Chap. XVII (pp. 235–246), "On the first Attitude of Wild Animals towards Man"; Chap. XVIII (pp. 247–260), "The larger Mammals of Patagonia,"— nine species formally treated. Also many references *passim* to the same species, and a reprint of "On a New Form of Puma from Patagonia" by Oldfield Thomas, pp. 334, 335. Many important illustrations from photographs, including skulls of Huemul, and colored plates of the Huemul in summer coat, the Cordillera Wolf, and Pearson's Puma.

Rengger, J. R.

1830 Naturgeschichte | der | Saeugethiere | von | Paraguay, | von | Dr. J. R. Rengger. | — Basel, | in der Schweighauserschen Buchhandlung | 1830. — 8vo, pp. i–xvi + 1–394.

Saint-Loup, Rémy.

1895 Notes sur l'anatomie du Mara (*Dolichotis patagonica* Desm.) (Bull. Mus. d'Hist. Nat. Paris, I, 1895, pp. 143–145).

Saint-Loup, Rémy.

1898 Une bonne espèce, á propos du *Dolichotis salinicola* (Burm.) (Comun. Mus. Buenos Aires, I, 1898, p. 43).

Sclater, P. L.

1866 [A young living "male Sea-Bear (*Otaria hookeri*" = *Otaria jubata* auct.) captured near Cape Horn, June, 1862] (P. Z. S., 1866, p. 80).

Afterwards the basis of Murie's memoir on the anatomy of this species. *Cf.* Murie, 1872–1874.

1868 [A young living female Sea-Lion (*Otaria jubata*), from the Falkland Islands, etc.] (P. Z. S., 1868, pp. 527–529).

1873 Remarks on *Cervus chilensis* and *Cervus antisiensis* (Ann. & Mag. Nat. Hist. (4), XI, March, 1873, pp. 213, 214).

Cervus leucotis Gray identified with *Cervus chilensis* Gay & Gervais, and *Anomalocera huamel*, *Xenalaphus hucmel* and *Xenelaphus leucotis* Gray with *Cervus antisiensis* D'Orbigny.

1870 [*Felis warwickii* Gray = *Felis geoffroyi* D'Orb. & Gerv.] (P. Z. S., 1870, pp. 796, 797).

1875 [The Huemul and its Allies.] (P. Z. S., 1875, pp. 44–47; fig. of left antler, p. 45).

Synonymy and discussion of (1) *Cervus chilensis*, (2) *Cervus antisiensis*, (3) *Cervus whitelyi*, and (4) *Cervus peruvianus*.

Scott, W. B.

1902 The Origin and Development of South American Mammals (Science, N. S., XV, No. 337, pp. 470, 471; Ann. N. York Acad. Sci., XV, 1903, 14, 15).

Abstract of a paper read before New York Academy of Sciences.

Thomas, Oldfield.

1880 Description of a new Species of *Reithrodon*, with Remarks on other Species of the Genus (P. Z. S., 1880, pp. 691–696, 4 text cuts).

Reithrodon alstoni, sp. nov. (= type of the genus *Sigmomys* Thomas, 1901), with a discussion of the relationships of *R. typicus*, *R. cuniculoides*, and *R. chinchilloides*.

1881 Account of the Zoological Collections made during the Survey of H.M.S. "Alert" in the Straits of Magellan and on the Coast of Patagonia. I, Mammalia. By Oldfield Thomas (P. Z. S., 1881, pp. 3–6).

An annotated list of 10 species; *Hesperomys* (*Calomys*) *coppingeri*, sp. nov., p. 4.

1889 Preliminary Notes on the Characters and Synonymy of the different Species of Otter (P. Z. S., 1889, pp. 190–200).

Important critical comment on the South American species, pp. 196–200.

1891 Notes on some Ungulate Mammals (P. Z. S., 1891, pp. 384–389).

On the generic and specific names of the Llamas and Alpaca, pp. 385–387.

1894 Descriptions of some new Neotropical Muridæ (Ann. & Mag. Nat. Hist. (6), XIV, Nov., 1894, pp. 346–366).

Includes, among numerous other species, *Acodon macronyx*, n. sp. (p. 362), from near Fort San Rafael, Province of Mendoza, east side of Andes.

1895 Descriptions of Four small Mammals from South America, including one belonging to the peculiar Marsupial Genus "*Hyracodon*" Tomes (Ann. & Mag. Nat. Hist. (6), XVI, Nov., 1895, pp. 367–370).

Includes *Acodon hirtus*, sp. nov. (p. 370), from Fort San Rafael, Mendoza.

Thomas, Oldfield.

1897 Descriptions of Four new South American Mammals (Ann. & Mag. Nat. Hist. (6), XX, Aug., 1897, pp. 118–221).

Oxymycterus lanosus, sp. nov., p. 118, from Monteith Bay, Straits of Magellan.

1897 On some small Mammals from Salta, N. Argentina (Ann. & Mag. Nat. Hist. (6), XX, Aug., 1897, pp. 214–218).

1898 On some Mammals obtained by the late Mr. Henry Durnford in Chubut, E. Patagonia (P. Z. S., 1898, pp. 210–212).

An annotated list of 7 species, with field notes by Mr. Durnford, collected on the coast about 60 miles south of the Rio Chubut (*cf.* Ibis, 1878, p. 391).

1901 On a new Form of Puma from Patagonia (Ann. & Mag. Nat. Hist. (7), VIII, Sept., 1901, pp. 188, 189).

Felis concolor pearsoni, subsp. nov.

1901 New Neotropical Mammals, with a Note on the Species of *Reithrodon* (Ann. & Mag. Nat. Hist. (7), VIII, Sept., 1901, pp. 246–255).

Note on the species of South American groove-toothed Muridæ, which are here separated into 3 genera (*Reithrodon, Euneomys, Sigmomys*) and 8 species.

1901 The name of the Viscacha (Proc. Biol. Soc. Washington, XIV, p. 25).

Viscaccia Schinz, 1825, the proper generic name for the Argentine Viscacha, also correcting Mr. J. G. Rehn, on *Viscaccica* Brandis ex Molina. Also *Lagidium viscacia* (Molina) the proper name of the Chilian Viscacha.

1901 On a Collection of Bats from [Central] Paraguay (Ann. & Mag. Nat. Hist. (7), VIII, Nov., 1901, pp. 435–443).

An annotated list of 19 species, the collection including topotypes of 8 of Azara's species.

1902 On Mammals from the Serra do Mar of Paraná, collected by Mr. Alphonse Robert (Ann. & Mag. Nat. Hist. (7), IX, Jan., 1902, pp. 59–64).

Annotated list of 18 spp.; *Akodon serrensis, Coendou roberti*, spp. nov.

1902 On Mammals collected by Mr. Perry O. Simonds on the southern part of the Bolivian Plateau (Ann. & Mag. Nat. Hist. (7), IX, March 1902, pp. 222–230).

Annotated list of 17 spp.; *Phyllotis arenarius, P. hirtipes, Ctenomys frater, Kerodon niator pallidior*, spp. et subsp. nov.

1902 On Mammals collected at Cruz del Eje, Central Cordova, by Mr. P. O. Simons (Ann. & Mag. Nat. Hist. (7), IX, April, 1902, pp. 237–245).

An annotated list of 14 spp.; *Lasiurus borealis salinæ, Conepatus proteus, Eligmodontia griseoflava centralis, Ctenomys bergi, Dolichotis magellanicus centricola, Dasypus vellerosus pannosus*, spp. et subspp. nov. Note on the proper name of Azara's "Chauve-souris septième."

1902 The generic names of the Peccaries, Northern Fur Seal, and Sea-Leopard (Proc. Biol. Soc. Washington, XV, 1902, pp. 153–156).

Callorhinus and *Callirhinus* considered as "permissible variants" of one compound; *Stenorhinchus* held to be not invalidated by the earlier *Stenorhynchus* or *Stenorynchus* for the Leopard Seal.

1903 Notes on Neotropical Mammals of the Genera *Felis, Hapale, Oryzomys, Akodon*, and *Ctenomys*, with Descriptions of new Species (Ann. & Mag. Nat. Hist. (7), XII, Aug., 1903, pp. 234–243).

Thomas, Oldfield.

Chelemys (new subgen. of *Akodon*), p. 242. Type, *A. macronyx* Thomas. Also *Akodon suffusus*, sp. nov., p. 241, Southern Chubut, Patagonia; *Akodon* (*Chelemys*) *vestitus*, sp. nov. (p. 242), Southern Chubut, Patagonia.

Townsend, Charles H.

1899 Pelagic Sealing, with notes on the Fur Seals of Guadalupe, the Galapagos, and Lobos Islands (The Fur Seals and Fur Seal Islands of the North Pacific Ocean, Part III, pp. 223–274, pll. xxii–xxxv).

Important notes on the Guadalupe Island Fur Seal, pp. 265–272; and on the Galapagos Islands Fur Seal, pp. 272, 273; note on the Lobos Islands Fur Seal rookery, with a photograph (pl. xxxv) of a portion of the islands covered by seals.

Turner, William, and **Wm. C. Strettell Miller.**

1888 Report on the Seals collected during the Voyage of H.M.S. Challenger in the years 1873–76 (Zool. Challenger Exped., Part LXVIII, 1888, pp. 1–240, pll. 10).

Part I, Description of Genera and Species, pp. 3–54; Part II, Classification of the Pinnipedia, pp. 55–88; Part III, Brain of Elephant Seal and of Walrus, pp. 89–134; Part IV, Viscera of Elephant Seal, pp. 135–138. Appendix. The Myology of the Pinnipedia, by W. C. Strettell Miller, pp. 139–234.

The species here recognized are (1) *Macrorhinus leoninus*, (2) *Leptonychotes weddellii*, (3) *Otaria jubata*, (4) *Arctocephalus gazella*, (5) *Arctocephalus australis*.

Waterhouse, George R.

1837 Characters of New Species of the Genus *Mus*, from the Collection of Mr. Darwin (P. Z. S., 1837, 15–21, 27–32).

Twenty-two new species, four new subgenera, and two new genera.

1848 A | Natural History | of the | Mammalia. | By | George R. Waterhouse, | . . . . [= 3 lines of titles] Vol. II. | Containing the Order | Rodentia, or Gnawing Mammalia; | with | 22 illustrations engraved on steel, and engravings on wood. | London: Hippolyte Baillière, Publisher, 219 Regent Street; | . . . . [= 4 lines] 1848. — 8vo, pp. 1–500, pll. i–xxi + x*.

Includes the Patagonian Rodents, except the Muridæ.

Waterhouse, George R., and **Charles Darwin.**

1839 The | Zoology | of | the Voyage of H.M.S. Beagle, | under the command of Captain Fitzroy, R.N., | during the Years | 1832 to 1836. | Published with the approval of | the Lords Commissioners of Her Majesty's Treasury. | Edited and Superintended by | Charles Darwin, Esq., M.A., F.R.S., Sec. G. S. | Naturalist to the Expedition. |—| Part II. | Mammalia, | by | George R. Waterhouse, Esq. | Curator of the Zoological Society of London, etc., etc. |—| London: | Published by Smith, Elder and Co. 65 Cornhill. | MDCCCXXXIX. |—| 4to, pp. ix + v, + 97, pll. xxxv (32 col.). The first of the two half titles reads:

Mammalia, | Described by | George R. Waterhouse, Esq. | Curator of the Zoological Society of London, etc. etc. | with | a Notice of their Habits and Ranges, | by Charles Darwin, Esq., M.A., F.R.S. | Secretary to the Geological Society. | Illustrated by numerous coloured engravings.

Waterhouse, George R., and **Charles Darwin.**

The most important original source of information on Patagonian Mammals. In several cases Darwin's Patagonian specimens became the types of species described by Waterhouse in 1837, and here redescribed and to a large extent figured. Darwin's notes on their habits and ranges are invaluable.

Weddell, James.

1825 A | Voyage | towards | the South Pole, | performed in the years 1822–23. | Containing | an examination of the Antarctic Sea, | to the seventy-fourth degree of latitude: | and | A visit to Tierra del Fuego, | with a particular account of the inhabitants. | To which is added, | much useful information on the coasting navigation of | Cape Horn, and the adjacent lands, | with charts of harbours, &c. | — | By James Weddell, Esq. | Master in the Royal Navy. | — | London: | printed for | Longman, Hurst, Rees, Orme, Brown, and Green, | Paternoster-row. | 1825. — 8vo, pp. i–iv + 1–276, with maps, charts and other illustrations.

Contains much valuable information on the habits of the seals of southern South America and the islands to the southward, and their destruction for commercial purposes. Also first description (by Prof. Jameson) and figure of Weddell's Seal, which formed the basis of Lesson's *Otaria weddellii* (= *Leptonychotes weddellii*).

Wilson, Edward A.

1902 Notes on Antarctic Seals, collected during the Expedition of the 'Southern Cross' (Report Nat. Hist. Collections of the 'Southern Cross,' 1902, pp. 67–78, pll. ii–vi).

On the distribution and habits of *Leptonychotes weddellii* (pp. 69–71, pl. ii), *Ogmorhinus leptonyx* (pp. 71–73, pl. iii), *Lobodon carcinophagus* (pp. 74–76, pll. iv and v), *Ommatophoca rossii* (pp. 76–78, pl. vi), with colored plates of the animals.

PART II.

BATRACHIANS AND REPTILES.

BY

LEONHARD STEJNEGER,

U. S. NATIONAL MUSEUM.

AS might be expected, the collection of batrachians and reptiles brought home by Mr. Hatcher is not rich in species, for it contains only one of the former and seven of the latter. On the other hand, nearly all the species are represented by numerous specimens, so that in several cases the limits of the species could be better defined than heretofore. It was thus possible from this material to demonstrate the distinctness of two species described from the collections brought home by Charles Darwin, but later confounded and regarded as individual variations of a single species. Without the large series it would probably also have been impossible to establish the existence of the species which in the following pages is described as new.

Unfortunately, however, hardly any definite localities are given where the specimens were actually collected. Only three of the specimens were individually labeled, but in every jar there is one or more slips of paper with a note in lead pencil indicating the nature of the station or the general distribution of the species. In one jar, there are several notes of a more definite geographical significance, but unfortunately they refer to three different localities and dates, while the jar contained a large number of specimens belonging to two species. In order to preserve every scrap of evidence which may tend to fix the localities approximately I submit a list of the contents of each jar, as follows:

Jar.	Specimens.	Species.	Inscription on Paper Slips.
1.	6.	*Liolæmus lineomaculatus.*	"Common everywhere on pampas of Patagonia to alt. of 3,000 ft."
	6.	*Liolæmus hatcheri.*	

Jar.	Specimens.	Species.	Inscription on Paper Slips.
2.	2.	*Liolæmus hatcheri.*	"Among mate negra and mate verde, plains of Patagonia."
	12.	*Liolæmus kingii.*	
3.	15.	*Liolæmus kingii.*	"Common among basaltic rocks of Patagonia."
4.	5.	*Liolæmus kingii.*	"Among mate negra bushes."
	2.	*Liolæmus bibronii.*	
5.	3.	*Liolæmus hatcheri.*	"Common everywhere on pampas of Patagonia to alt. of 3,000 ft.
	34.	*Liolæmus lineomaculatus.*	
	13.	*Liolæmus kingii.*	

Of the specimens in this jar, one *L. lineomaculatus* and two *L. kingii* are enclosed each in a separate vial, in each of which there is a slip inscribed as follows:

(*a*) "'The Salinas' near mouth of Rio S. C. Patagonia, March 1, 1898. J. B. H." (*L. lineomaculatus.*)

(*b*) "North of Rio S. C. Patagonia, March, 1898. J. B. Hatcher." (*L. kingii.*)

(*c*) "North of Rio S. C. Patagonia, March, 1898. J. B. H." (*L. kingii.*)

6.	5.	*Liolæmus fitzingerii.*	"Among incense bushes in warm, sandy, well protected places." "North of S. C. river."
7.	6.	*Liolæmus fitzingerii.*	"Among incense bushes in warm, sandy, well protected places."
8.	10.	*Diplolæmus darwinii.*	"About margins of small salt lakes of Patagonia."
	2.	*Diplolæmus bibronii.*	
9.	3.	*Diplolæmus darwinii.*	"About margins of small salt lakes."
	2.	*Diplolæmus bibronii.*	
10.	4.	*Diplolæmus darwinii.*	"About margins of small salt lakes. Patagonia."
	5.	*Diplolæmus bibronii.*	
	1.	hybrid?	
11.	76.	*Paludicola bufonina.*	"In small streams of Patagonia, Straits of Magellan to Lake Buenos Aires."
	12.	Tadpoles.	

The "Rio S. C.," of jar 5, is unquestionably the Santa Cruz River. The month of March, 1898, mentioned on the labels in the vials in jar 5 found Mr. Hatcher on his second Patagonian expedition, between the mouth of the Santa Cruz River and Lake Buenos Aires. The only other note which I can connect with a definite locality is that found in jar 3, which states that the *Liolæmus kingii* is "common among basaltic rocks of Patagonia." After leaving the Rio Chico and turning northwards Mr. Hatcher struck these basaltic rocks, and from his "Narrative" (Rep. Princeton Univ. Exped. Patagonia, I, 1903, pp. 163–165) it is seen that he camped for some little time in their neighborhood, collecting and exploring. "While encamped at this locality, I climbed one day to the summit of the basaltic platform and travelled for a considerable distance over its deeply fractured and cavernous surface. . . . By turning over a number of large detached pieces of lava I procured a number of beetles, crickets, spiders, a centipede and a scorpion, while *small black lizards were not wanting*." These were undoubtedly *Liolæmus kingii*, and the 15 specimens in jar 3 were probably secured at that place. The whole collection submitted to me for report has the appearance of having been made at practically the same time, and is probably all made during the second expedition. The few facts gathered from the labels indicate the country north of Santa Cruz and it is probably legitimate to conclude that most of the specimens were obtained at the salt lakes near Santa Cruz and in the country between and east of the lakes Pueyrredon and Buenos Aires, consequently within a district bounded by latitudes 47° and 48° south, and longitudes 70° and 70° 30′ west from Greenwich.

It seems therefore certain that the collection contains no specimens of the "great variety of small lizards of varying size, shape and color" which Hatcher speaks of on p. 84 (*vol. cit.*) as appearing about the cliffs and over the pampas near Corriken Aike (on the coast, about 51° 10′ south lat.). This is particularly unfortunate, as Mr. Barnum Brown, in reviewing the volume in question (in Amer. Natural., XXXVII, Nov., 1903, pp. 799–800) makes the statement that "this observation on lizards should have been confined to that part of Patagonia north of the Rio Santa Cruz, for this river forms the natural southern boundary line for lizards as well as of armadillos though a few have been scattered south of it by man." This statement is clearly fallacious as to the southern limits of the lizards. I know that Mr. Hatcher prepared a refutation of it based on his own

personal experience, but I am not sure that he ever published it. The Swedish expedition, 1895–1896, under Dr. Otto Nordenskiöld, however, collected lizards in southern Patagonia, upon which Mr. L. G. Andersson has reported (Oefvers. Vetensk. Akad. Fœrh. Stockholm, 1898, No. 7, pp. 457–462). He records two species of *Liolæmus* from Puerto Gallegos, and one from Coyle, the former locality a little south of the other, just north of Corriken Aike, where Hatcher made his observation. Furthermore, the Swedish expedition found two species of lizards as far south as the Rio Grande, on the east coast of Tierra del Fuego. It may be added that there are specimens of *Liolæmus magellanicus* in the British Museum from several localities on Magellan Strait. As a matter of fact the latter species is confined to this part of Patagonia and probably does not reach northward to within 60 miles of the Rio Santa Cruz, which Mr. Brown would make the southern limit of the lizards in South America. The fact that the country south of the Santa Cruz possesses a peculiar species shows that it has not been introduced by man.

Order SALIENTIA.

PALUDICOLA BUFONINA (Bell).

1843. *Pleurodema bufoninum* BELL, Zool. Beagle, Rept., p. 39, pl. xvii, fig. 5 (type locality, Port Desire, Patagonia; types in Brit. Mus.; Darwin, collector).—*Paludicola bufonina* BURMEISTER, Anal. Mus. Nac. Buenos Aires, III, 1888, p. 251.

1858. *Pleurodema bufonium* GUENTHER, Cat. Batr. Sal. Brit. Mus., p. 31 (err. typ.).—*Paludicola bufonia* BOULENGER, Cat. Batr. Sal. Brit. Mus., 1882, p. 230 (Port Desire).—? KOSLOWSKY, Rev. Mus. La Plata, VI, 1895, p. 360.—BERG, Anal. Mus. Nac. Buenos Aires, V, Dec., 1896, p. 169 (Isla de Pavón, Rio Sta. Cruz; Chubut).—ANDERSSON, Oefvers. Vet. Akad. Fœrh. Stockholm, 1898, No. 7, p. 462 (Chubut River, Patagonia).

A large number of specimens (88), including tadpoles, were collected by the expedition. As indicated above, the exact locality or localities

where these specimens were collected is not given, nor the time of their capture, the only note accompanying them being to the effect that they occur "in small streams of Patagonia, Straits of Magellan to Lake Buenos Aires." While I have expressed the opinion above, that most of the lizards were collected north of the Santa Cruz, after March 1, 1898, there are reasons for believing that most of these batrachians were collected at a considerably earlier season. Not only is a large proportion of the specimens, tadpoles and young ones, having just finished their metamorphosis, but many of the males have well-developed nuptial asperities on the inner finger. This, in connection with the reference to the Straits of Magellan on the label, makes it exceedingly probable that the specimens in nuptial and breeding condition were collected during the latter part of December, 1897, at the camp established by Mr. Hatcher on the Rio de las Minas, four miles above the town of Punta Arenas. In this camp in the forest Mr. Hatcher remained for nearly two weeks occupied in collecting and study (Narrat., p. 158).

While there is thus established a probable locality for a large number of the specimens, there is no telling where the others were collected. This is the more to be regretted as there may possibly be two forms represented in the lot, one with strongly developed webs, lobed toes, and a tarsal fold, and another with nearly cylindrical toes, scarcely any web, and no tarsal fold. In other respects the two forms seem to be identical, even in the size of the lumbar glands, except that a greater proportion of the specimens with rudimentary webs have a light median dorsal stripe. I am inclined to regard the difference as seasonal, however, inasmuch as all the males with the nuptial pads on the inner finger have large webs and even an indication of lobes or fringe on the fingers.

These fringes or lobes are very much like those of the coot, as even the outside of the outer toes has a lobe. The fringe is continued past the inner metatarsal tubercle as a tarsal fold.

The lumbar glands in both (seasonal?) forms and sexes are large, the length equalling the distance from tip of snout to anterior or posterior border of tympanum.

The hind legs are rather short, as the tibio-tarsal articulation of the leg carried forward along the side does not reach the tympanum.

Among the specimens there are twelve tadpoles in various stages of development. As I have seen no description of the tadpole of this species,

I append one of a specimen in the third period. None of the specimens are in a very good state of preservation.

Description of Tadpole.—Length of body about once and a half its width and two-thirds the length of the tail; nostrils about equidistant from tip of snout and from eye; distance between eyes more than twice as great as distance between nostrils and much greater than width of mouth; distance between nostrils shorter than their distance from eye or diameter of the latter; spiraculum on left side, directed backwards, situated nearer to the eye than to the insertion of the hind leg; anus median; tail about four times as long as deep, ending in an obtuse point; both upper and lower crests confined to the tail and nearly equal in depth; depth of muscular part of tail at its base a little more than two-thirds of the greatest total depth.

Beak with black edges, denticulation of cutting edges much finer than of dental rows; lips papillate, except on the median half of the upper lip; the series of labial teeth $\frac{2}{3}$; outer series of upper lip long and uninterrupted, followed by a short series on each side; the two inner series of lower lip long, occupying the whole width of the lip, the outermost one-third to one-half shorter; the two outer series uninterrupted, the inner one also continuous or narrowly interrupted in the middle.

Lines of muciferous ducts cannot be traced on account of the poor preservation of the specimens.

Color (in alcohol) olive gray, paler underneath, tail indistinctly mottled with dusky.

The specimen described measures:

Total length	50 mm.
Body	20 "
Tail	30 "
Width of body	14 "
Depth of tail	8 "

Class II. REPTILIA.

Order SQUAMATA.

Suborder *SAURIA*.

LIOLÆMUS LINEOMACULATUS Boulenger.

1842. *Proctotretus kingii* BELL, Zool. Beagle, Rept., p. 13 (part), pl. vi, fig. 2 (not pl. vi, fig. 1).

1885. *Liolæmus lineomaculatus* BOULENGER, Cat. Liz. Brit. Mus., II, p. 149 (type locality, Patagonia; types in Brit. Mus.; Darwin, collector). —ANDERSSON, Oefvers. Vet. Akad. Fœrh., Stockholm, 1898, No. 7, p. 461 (Puerto Gallegos and Santa Cruz, Patagonia).—BURMEISTER, Anal. Mus. Nac. Buenos Aires, III, 1888, p. 250.—KOSLOWSKY, Rev. Mus. La Plata, VI, 1895, p. 363 (Cordilleras de Rioja); VII, ii, 1896, p. 450 (Chubut).

L. lineomaculatus is probably the northern representative of *L. magellanicus*. The latter is recorded from Tierra del Fuego and from the Straits of Magellan. According to Andersson both forms were collected together at Puerto Gallegos by the Nordenskiöld expedition, in 1895.

One specimen only out of the 40 collected by Mr. Hatcher has a definite locality assigned to it, as stated above, *viz.*, the one from "The Salinas" near mouth of the Rio Santa Cruz. The two *L. kingii* in the same jar from "north of Rio Santa Cruz," were also collected in March, 1898, and the uniformity of the series makes it appear probable that all were secured in the same neighborhood, *i. e.*, between Santa Cruz and Lake Buenos Aires. According to Hatcher they are common everywhere on the pampas up to an altitude of 3,000 feet. This statement includes *Liolæmus hatcheri* also, and as the two species are very much alike superficially, it remains doubtful whether they occur together or perhaps at different levels.

The series brought home by Mr. Hatcher shows great uniformity in character, and the young are practically like the adults. The greatest variation appears to be in the coloration of the underside, which is more or less marbled with dark gray lines, most distinctly on the throat. Many specimens are nearly uniform whitish underneath, while on the other hand

in several of the young specimens this dusky marbling is much denser and darker. The upper surface shows the regular pattern of this and related spots, but in one adult specimen the black cross bars show a tendency to fuse into longitudinal bands in the space between the median dorsal pale line and the next one on each side. The three dorsal bands are sharply defined and present in all the specimens.

Anal pores appear to be entirely absent in this species.

Liolæmus hatcheri, sp. nov.

Diagnosis. — Sides of neck folded, covered by imbricated, pointed scales, smaller than those on back; scales on middle of back not larger than those on sides of belly; ventral scales not larger than dorsals; lateral scales but slightly smaller than dorsals and, like them, strongly keeled and mucronate; 50–58 scales round the middle of the body; a distinct patch of enlarged pointed scales on hinder side of thighs; males with no anal pores; coloration like *L. magellanicus* and *L. lineomaculatus*.

Type. — U. S. Nat. Mus. No. 36,912; collected north of Santa Cruz River (?), March or April (?) 1898, by J. B. Hatcher.

Habitat. — Southern Patagonia: Territory of Santa Cruz.

This new species is nearly allied to *L. magellanicus*, *L. lineomaculatus* and *L. bibronii*, from all of which it differs in the enlarged scales on the posterior aspect of the thighs. It agrees with the first mentioned and the last mentioned species in the mucronate dorsal scales, but in the number of scales around the body it differs chiefly from *L. magellanicus*, which has only 40–44. The coloration is also very similar to that of the latter, and *L. lineomaculatus*, except that the underside is more heavily marbled with blackish. The large specimen which I have selected as type even has the underside solid black and approaches also in the coloration of the upper surface somewhat that of *L. kingii*, with which it was associated in the same jar (No. 2), but the latter has much smaller scales, and hinder side of thighs is uniformly granular. In having the enlarged scales on the posterior aspect of the thigh our new species agrees well with *L. fitzingerii*, but while the latter has even smaller and less pointed scales than *L. kingii*, *L. hatcheri* has them much larger and much more pointed. Finally *L. hatcheri* agrees with *L. lineomaculatus* only in the male being without anal pores, there being 2 to 3 in *L. bibronii*, 3 to 5 in *L. magellanicus*, and 6 to 8 in *L. kingii*.

L. hatcheri, as far as size is concerned, seems to hold an intermediate position between *L. lineomaculatus* and *L. kingii*, being larger than the former, but smaller than the latter. The type, which is an adult male, with a reproduced tail, shows the following:

DIMENSIONS.

Total length (tail reproduced)	97 mm.
Snout to vent	67 "
Snout to ear	14 "
Width of head	14 "
Fore leg	21 "
Hind leg	32 "
Axilla to groin	30 "

In this case, even more than in that of the other species, it is highly to be regretted that not even a single specimen has a locality label attached to it. The fact that the specimens of *L. hatcheri* were found in the jars with *L. kingii* and *L. lineomaculatus*, which we have good reasons for believing were collected north of the Rio Santa Cruz, makes it probable that the new species also comes from the same part of Patagonia.

LIOLÆMUS KINGII (Bell).

1843. *Proctotretus kingii* BELL, Zool. Beagle, Rept., p. 13 (part), pl. vi, fig. 1 (type locality, Port Desire, Patagonia; types in Brit. Mus.; Capt. King, collector). — *Liolæmus kingii* BOULENGER, Cat. Liz. Brit. Mus., II, 1885, p. 149 (Chili, Patagonia). — BURMEISTER, Anal. Mus. Nac. Buenos Aires, III, 1888, p. 250. — *Liolæmus kingi* KOSLOWSKY, Rev. Mus. La Plata, VII, ii, 1896, p. 450 (Chubut).

Forty-five specimens of this species indicate that Hatcher was correct in stating that it is common. It is probable, however, that it does not extend much beyond the Santa Cruz River, if at all. As mentioned above, Hatcher's reference to it as "common among basaltic rocks" probably relates more particularly to the basaltic platform north of the Rio Chico, where he collected in March, 1898.

There is a number of quite young specimens in the lot. They agree very well in character with the adults. In the same jar (No. 5) there was also a number of young *L. lineomaculatus*. Even the youngest of these

can be told apart at a glance notwithstanding their general similarity, as the young of the latter have the black dorsal markings invariably interrupted by the three distinct dorsal pale lines, while in the latter there are no distinct lines and the black markings are continuous across the back. Moreover, *L. kingii* has noticeably larger and flatter head-shields, and much smaller dorsal scales.

Liolæmus bibronii (Bell).

1843. *Proctotretus bibronii* Bell, Zool. Beagle, Rept., p. 6, pl. iii, figs. 1–1*b* (type locality, Port Desire, Patagonia; type in Brit. Mus.; Darwin, collector). — *Liolæmus bibronii* Gray, Cat. Liz. Brit. Mus., 1845, p. 212 (Port Desire; Chili). — *Liolæmus bibronii* Boulenger, Cat. Liz. Brit. Mus., II, 1885, p. 146 (Chili; Patagonia). — Burmeister, Anal. Mus. Nac. Buenos Aires, III, 1888, p. 250. — *Liolæmus bibroni* Koslowsky, Rev. Mus. La Plata, VII, ii, 1896, p. 450 (Chubut; Neuquen). — Andersson, Oefvers. Vet. Akad. Fœrh. Stockholm, 1898, No. 7, p. 461 (Patagonia).

As Mr. Hatcher obtained only two specimens of this species, it is probably permissible to conclude that it did not occur commonly in the localities where he did most of his collecting. These specimens were in a jar with five *L. kingii* taken "among mate negra bushes." As the latter almost certainly were collected north of the Rio Santa Cruz, the *L. bibronii* probably also came from that part of his route in 1898.

The specimens present no features of special interest. The dark spots on the upper surface show a distinct tendency to fuse into longitudinal lines.

Liolæmus fitzingerii (Duméril and Bibron).

1837. *Proctotretus fitzingerii* Duméril and Bibron, Erpét. Gén., IV, p. 286 (part; type locality, Chili; types in Paris Mus.). — Bell, Zool. Beagle, Rept., 1843, p. 11, pl. v, figs 1–1*b* (Port Desire and Santa Cruz, Patagonia). — *Liolæmus fitzingeri* Boulenger, Cat. Liz. Brit. Mus., II, 1885, p. 150 (Chili; Patagonia). — Burmeister, Anal. Mus. Nac. Buenos Aires, III, 1888, p. 250 (Patagonia). — Koslowsky, Rev. Mus. La. Plata, VI, 1895, p. 364 (Catamarca); VII, ii, 1896, p. 450 (Chubut; Neuquen; Rio Negro); — Berg, Anal. Mus. Nac. Buenos Aires, VI, 1898, p. 6 (Santa Cruz). — Andersson,

Oefvers. Vet. Akak. Fœrh. Stockholm, 1898, No. 7, p. 461 (Puerto Madryn, Chubut, Patagonia).

1857. *Eulæmus affinis* GIRARD, Proc. Phila. Acad., 1857 (p. 198); Herpet. U. S. Expl. Exped., 1858, p. 365 (type localities, Port Desire and Santa Cruz, Patagonia; based on Bell's description).

1888. *Liolæmus melanops* BURMEISTER, Anal. Mus. Nac. Buenos Aires, III, p. 252 (type locality, Quelé-Curá, Patagonia).

The eleven specimens brought home by Mr. Hatcher were probably collected in the same neighborhood "among incense bushes in warm, sandy, well-protected places" "north of the Santa Cruz river." This species therefore in all probability does not extend southward beyond the river mentioned.

The majority of the specimens have no azygos frontal, but on the contrary a well-developed double row of shields between the orbits. The inner row of supraocular shields in most specimens is greatly enlarged transversely; in a few specimens, however, they are but slightly differentiated from the others. The postfemoral patch of enlarged scales varies considerably in size and development, but is always present. The coloration is quite characteristic, viz., olive above with ill-defined rusty spots; the extent of the black on the underside is variable, but there is always at least a large black patch on the underside of the neck.

DIPLOLÆMUS BIBRONII Bell.

1843. *Diplolæmus bibronii* BELL, Zool. Beagle, Rept., p. 21, pl. xi (type locality, Port Desire, Patagonia; types in Brit. Mus.; Darwin, collector). — DUMÉRIL, Cat. Méth. Rept. Mus. Paris, I, 1851, p. 68 (Port Desire).

1882. *Diplolæmus darwinii* BOULENGER, Cat. Liz. Brit. Mus., II, p. 126 (part: types) (not of Bell). — ANDERSSON, Oefvers. Vet. Akad. Fœrh. Stockholm, 1898, No. 7, p. 460 (part: Santa Cruz, Patagonia).

Boulenger has united Bell's *D. bibronii* and *D. darwinii* without giving his reasons for so doing. The large series at hand seems to prove conclusively, however, that we have to do with two distinct though very similar species. The differences are quite marked both in scutellation and coloration, and males and females, adults and young are equally well characterized. As the series consists of 27 specimens it must be consid-

ered beyond a shadow of doubt that the differences are not due to sex or age.

Diplolæmus bibronii is easily distinguished by the larger scales on the head. The difference is particularly striking in the scales covering the loreal triangle, the space between the suboculars and supralabials, and the series between the lower labials and the malar series. The nostril also appears nearer the rostral, but this is probably partly due to its larger size and the larger, hence fewer, scales between it and the rostral.

Where we have to do with scales so reduced in size as in this genus it is difficult to establish a scale formula which is not breached by one or more specimens. It is therefore noteworthy that in the whole series only one *D. bibronii* has a scale interpolated between the first lower labial and the first chin-shield, a condition found in all the *D. darwinii* before me, while in all the other specimens of *D. bibronii* these shields are in contact. In the latter, moreover, the tail is also proportionally shorter and the toes less elongate, though the last mentioned character is subject to considerable variation.

The difference in coloration, which is quite striking and equally characteristic of the adult and the young specimens, is absolutely coincident with the structural differences and even more noticeable. It is not necessary to describe these differences here, as they are very well brought out in the original descriptions by Bell, as well as in the figures accompanying them.

All that Hatcher says about their occurrence in Patagonia is that they are found "about margins of small salt lakes." It is probable, however, that they were collected not far from the Santa Cruz, or from the coast.

Diplolæmus darwinii Bell.

1843. *Diplolæmus darwinii* Bell, Zool. Beagle, Rept., p. 20, pl. x (type locality, Port Desire, coast of Patagonia; types in Brit. Mus.; Darwin, collector). — Boulenger, Cat. Liz. Brit. Mus., II, 1885, p. 126 (part: types). — Burmeister, Anal. Mus. Nac. Buenos Aires, III, 1888, p. 250. — *Diplolæmus darwini* Koslowsky, Rev. Mus. La Plata, VII, ii, 1896, p. 448 (Sta. Cruz; Chubut; Rio Negro; Neuquen). — Andersson, Oefvers. Vet. Akad. Fœrh. Stockholm, 1898, No. 7, p. 460 (part: Cerro Toro, South Patagonia).

Apparently this species lives with the foregoing "about the margins

of small salt lakes," though they probably occupy somewhat different stations. That two so nearly allied species should live together in so close neighborhood without occasionally producing hybrids would be highly improbable. The wonder is really that they are as pure bred as they appear to be, and one would like to know the nature of the "isolation" or "segregation" which accomplishes this result. That interbreeding takes place occasionally, however, seems indicated by a specimen brought home by Mr. Hatcher, which in many respects shows evidence of being intermediate between the otherwise typical specimens of both species.

This specimen (from jar 10) has somewhat smaller head scales than *D. bibronii*, but larger than extreme *D. darwinii*, though there is a well-developed shield between first lower labial and first chin-shield behind the mental as in the latter species. The coloration is also intermediate inasmuch as the cinnamon or rather vinaceous ground color of *D. darwinii* is absent, while its broad semilunar white spots behind each dorsal black bar on each side of the back are exactly as in the latter. The dense sprinkling of the upper ground color with dusky and the broad, distinct blackish cross bands on arms and legs are again indicative of *D. bibronii*, while the absence of the characteristic fish-hook mark on the nape of the latter is absent and replaced by the equally characteristic pair of spots of *D. darwinii*. The black cross-bars on the back are located slightly differently in the two species, but their number is apparently the same. Here, however, is a somewhat surprising deviation from both in the supposed hybrid, inasmuch as it has one regular cross-bar more than either.

This last feature might lead to the suspicion that we have before us the possible representative of a third form. It is then very unfortunate that the exact locality of each specimen is unknown. Under these circumstances there is nothing else to be done than to call attention to the facts as represented above and to leave the clearing up of this, with so many other questions, to the future explorers of Patagonia.

BIBLIOGRAPHY.

PART III.

THE FRESH-WATER FISHES OF PATAGONIA AND AN EXAMINATION OF THE ARCHIPLATA-ARCHHELENIS THEORY.

BY

CARL H. EIGENMANN,

INDIANA UNIVERSITY.

PROFESSOR W. B. SCOTT,
PRINCETON, NEW JERSEY.

Dear Sir: I enclose the MS. of my report on the fishes collected by the late J. B. Hatcher in Patagonia. Instead of confining my report to the few specimens collected by Mr. Hatcher I have utilized, as far as possible, the knowledge gained from previous collections, and have dealt monographically with the fresh-water fishes of the area south of the line joining the mouth of the Rio Negro and Santiago, Chili. Ichthyologically this area constitutes a faunal unit sharply defined from temperate and tropical America to the north of it.

Since 1887 I have been busied more or less with the fresh-water fishes of South America, and the present opportunity seemed to me the best to use our knowledge concerning them to test the claims of the Archiplata-Archhelenis theory. This theory must stand or fall by the evidence of the fresh-water fishes. The task proved much more onerous than expected, but I feel amply repaid by the definite ideas gained by this review.

It seems quite certain: (*a*) that tropical America obtained the elements of its fauna in common with Africa before the Tertiaries, from some insignificant common ground inhabited by Cichlids, Characins, and Catfishes (Nematognaths) and perhaps types of wide distribution which remain only as relicts; (*b*) that tropical America has not been accessible and received few, if any, immigrants from other land areas since that time; but (*c*) that

the three types mentioned have undergone unparalleled adaptive radiation in the growing and metamorphosing continent, the Cichlids developing about 150 known species, the Characins 500, besides differentiating the Gymnotids, and the Catfishes, 500 or more species, distributed in several autochthonous families.

The grounds for all of these conclusions together with their corollaries you will find set forth in detail, all of which I hope will meet with your approval.

This report is divided therefore into a section dealing with The Fresh-water Fishes of Patagonia, a section dealing with the Archiplata-Archhelenis theory and a section listing all of the fresh-water fishes of South and Middle America.

I must at this place acknowledge the most courteous assistance received from Mr. Richard Rathbun and Mr. Barton A. Bean, of the United States National Museum; Dr. G. A. Boulenger and Mr. C. T. Regan, of the British Museum; Dr. Franz Steindachner, of the K. K. Museum of Vienna; Mr. S. Henshaw, of the Museum of Comparative Zoölogy, and Dr. R. Gestro, of the Museo Civico di Storia Naturale, Genoa, Italy.

Respectfully submitted,

CARL H. EIGENMANN,
Professor of Zoölogy, Indiana University, and Director of the Indiana University Biological Station.

THE FRESH-WATER FISHES OF PATAGONIA.

INTRODUCTION.

The interest in the Patagonian fresh-water fish fauna is entirely out of proportion to its diversity and centers largely in its origin. Only about twenty-nine species of fishes are known to live or enter the fresh waters south of the line joining Valparaiso and Bahia Blanca. These few species fall, according to their origin, into four distinct groups.

1. Immigrants from the sea are: (*a*) in the process of acclimatization, species of *Menidia* and *Atherinopsis*, or (*b*) may be looked upon as long established, species of *Percichthys* and *Percilia*. Members of *a* are found in all the rivers; members of *b* are found in the north chiefly, but reach the Santa Cruz river.

2. Immigrants from the fresh waters on the north: a very small overflow from the extremely rich fauna to the north and still retaining their generic affinity with northern forms. Here belong the species of the genera *Cheirodon* and *Astyanax*, which are very widely distributed in tropical South America and are not known to extend much south of the Rio Negro. Here also belongs *Hatcheria*, a southern modification of the widely distributed *Pygidium*.

3. Autochthons, or of doubtful origin. Here belongs the highly interesting *Diplomyste*, which is found on the northern border of Patagonia, but is not a derivative of the tropical American fauna. It is a relict of the original catfishes, in which the maxillary is still functional as a tooth bearer. Here belongs also *Nematogenys*, a catfish related to *Pygidium*. Like the members of group 2, these species are confined to the northern fringe of the Patagonian area.

4. There remain unaccounted for the members of the *Aplochitonidæ*, *Galaxiidæ* and *Petromyzonidæ*, chiefly of southern Patagonia. The two former Boulenger puts in his Haplomi, an order of odds and ends of fishes, containing such relicts as the *Percopsidæ*, *Amblyopsidæ* of North

America, *Kneriidæ* of Africa, *Dalliidæ* of Alaska and Siberia, and the dominant *Pœciliidæ* of the tropical fresh waters, the *Esocidæ* of the north temperate zone, and the *Scopelidæ* of the deep sea. By Gill, on the other hand, they are placed in the order of Malacopterygii with the Clupeoids and Salmonoids.

Of the *Aplochitonidæ* there are two genera, *Aplochiton* with an undetermined number of species in the Patagonian region, and *Prototroctes* with three species, one in Queensland, one in South Australia and one in New Zealand.

Of the *Galaxiidæ* there are two genera, *Neochanna* (*apoda*) from New Zealand, where it frequently burrows in damp clay away from water, and *Galaxias*, with about 30 species from New Zealand, New South Wales, South Australia, Tasmania, Cape of Good Hope, southern South America and the Falkland Islands. The *Petromyzonidæ* are found in all temperate fresh waters and seas, in both the northern and southern hemispheres.

The distribution of the two former families is of interest in connection with the theory of a former antarctic continent connecting the land masses in which they are found. In favor of a former land connection it may be argued, and with justice, that while these species descend to the sea, the probability that any pair of individuals should migrate from Cape Horn to New Zealand or vice versa is highly improbable. (This objection loses some weight if they spawn in the sea, as is reported.) There are no intermediate places that might be colonized and serve as new centers of distribution. It may further be urged that these species could readily have been distributed to their present homes by migration from stream to stream along a continuous coast line or on a land wave moving from one place to another. An obvious objection comes from the paucity of the forms with this peculiar distribution. If there was a continental mass connecting South America with New Zealand and Australia fit to be inhabited by fishes, there must have been an abundant and diverse fish fauna which has disappeared. If the antarctic continent depended entirely for its existence on the evidence from the distribution of the fresh water fishes, its existence would be very highly theoretical and precarious. Concerning the distribution of *Galaxias*, Boulenger says:

"The fact that certain species of *Galaxias* live both in fresh water and in the ocean suffices to explain the curious distribution of this small family without the necessity of appealing to the existence in the past of an

antarctic continent. It is probable that the Galaxiidæ were formerly distributed as marine forms about the entire globe south of the tropic of Capricorn and that certain species on adapting themselves entirely to a life in freshwater have become localized in points as widely isolated from each other as those in which we know them now." See also the quotation under *Galaxias*, p. 271.

However, the evidence from other sources of a former land connection has become conclusive, and I am of the opinion that during the submergence of large parts of Patagonia during the late Pliocene the formerly abundant freshwater fauna became exterminated with the exception of those forms that were indifferently freshwater or marine.

The Petromyzonidæ offer still another difficulty. There is no place on the American continents between the Mexican plateau and Central Chili that harbors any species of the family. The northern and southern species belong to distinct genera. At least two of the South American genera are peculiar, while two others are found in Australia and New Zealand.

A comparison of the Atlantic and the Pacific regions of Patagonia shows the two slopes to be largely inhabited by the same forms, a fact easily explained by the character of the species (anadromous or indifferently marine or aquatic) together with the continuous way by ocean and series of streams emptying at intervals between the Rio Negro and Santiago.

A comparison of the species inhabiting the southern part of the region from the Rio Santa Cruz south and the northern part from the Rio Santa Cruz to the north shows us that the southern part of Patagonia is inhabited by an extreme fauna limited to *Galaxias*, *Aplochiton*, *Geotria* and *Exomegas*.

To these are added on the north, on both sides, *Percichthys*, *Diplomyste* and *Pygidium*, and on the west alone, *Percilia*, *Nematogenys* and *Cheirodon*. On the east *Astyanax* and *Gymnocharacinus* appear before the La Plata fauna proper is reached. They are outliers of the largest of the South American families, the *Characidæ*.

BOUNDARY BETWEEN THE BRAZILIAN AND PATAGONIAN REGIONS.

The definitive boundary between these regions has not been determined, since little is known of the fauna of the Rio Negro and nothing from the region about 500 miles wide extending north from a line connecting the

mouth of the Rio Negro with Santiago, Chili. No systematic collecting has been done in the Rio Negro, but the few specimens recorded from this region are, with the exception of *Astyanax*, Patagonian; on the other hand, the few specimens recorded from just south of Buenos Aires are Brazilian.

The southern boundary of the Brazilian fauna has been extended on the east by the La Plata-Paraguay river. The headwaters of this river, the Parana and especially the Paraguay, are in contact with the southern tributaries of the Amazon, and have opened a way for the southward migration of equatorial forms like members of the *Gymnotidæ*, the *Serrasalmoninæ* and the *Characinæ*, which have not succeeded in migrating so far south along the east coast, where there does not exist a continuous water way. (See the chapter on southeastern Brazil.) The distance which the La Plata-Paraguay has extended the tropical fauna can be measured by comparing the fauna of Buenos Aires, which is composed entirely of Amazonian types, with the fauna of the Rio Grande at the boundary of the United States, whose mouth is 10° nearer the equator and the Amazon than Buenos Aires, and only 6½ per cent. of whose fauna is made up of equatorial types. This southward extension of the equatorial fauna was also facilitated by the entire absence of competitors. The entire fauna of the Parahyba near Rio de Janeiro is equatorial, while only 15+per cent. of the Rio Panuco fauna in the same latitude in Mexico is equatorial, the rest being mostly intrusives from the north. Similar irregularities in the distribution of species are introduced in other parts of the globe, where a river has a north and south extent over different climates or regions, as in the case of the Nile.

On the Pacific slope one genus of tropical lowland forms, *Cheirodon*, reaches the southern limit of the Chilian plateau, and one mountain genus, *Pygidium*, reaches as far south as Santiago, Chili, and it is continued still further south as *Hatcheria*. The southern boundary of the northern fauna is here, so far as records show, the desert of Atacama. The southern boundary of the Brazilian fauna seems to be determined by climate and the means of ready migration.

The factors determining the northward extent of the Patagonian fauna are not so apparent. With the exception of *Geotria* and *Exomegas*, no Patagonian forms reach so far north as Buenos Aires on the Atlantic side; on the Pacific side the fauna in the latitude of Buenos Aires is still distinctly Patagonian.

SYNOPSIS OF THE FRESH-WATER FISHES OF PATAGONIA.

Class I. MARSIPOBRANCHII.

= *Marsipobranchii* Bonaparte, Nuovi Annali delle Sci. Nat. t. 2, 1838; Müller, Abhandl. K. Akad. Wiss. Berlin, 1844.
< *Myzontes* Agassiz, Contrib. to Nat. Hist. of U. S., I, 187, 1857.
= *Dermopteri* Cope, Proc. Acad. Nat. Sci. Phila. 1868, 256.
= *Cyclostoma* Gegenbaur, Grundriss der vergl. Anat. 577, 1870.
= *Cyclostomata* Schmidt, Handb. der vergleich. Anat. 6, Aufl. 259, 1872.
= *Marsipobranchiates* Gill, Arrangement Fam. Fishes, IX, 25, 1872.

Skeleton cartilaginous; skull imperfectly developed, not separate from the vertebral column; no jaws, no limbs, no shoulder girdle, no innominates; no branchial arches, gills in sacks, 6 or more; nares single, median; mouth suctorial, subcircular; no bulbus arteriosus; alimentary canal straight, simple, without cœcal appendages or pancreas; an abdominal pore; development with a metamorphosis.

Order I. HYPEROARTII.

= *Hyperoartia* Müller, Abhandl. K. Akad. Wiss., Berlin, 1844.

Eel-shaped; nasal duct a blind sack, not penetrating the palate; gill-opening close behind the head, communicating with a common branchial passage which opens into the pharynx; intestines with a spiral valve.

Family I. *PETROMYZONIDÆ.*

= *Lampredini* Rafinesque, Indice d'Ittilog. Siciliana, 1810.
= *Petromyzonidæ* Bonaparte, Nuovi Annali delle Sci. Nat. II, 133, 1838; Jordan & Evermann, Bull. U. S. Nat. Mus. 47, 8, 1896.
= *Petromyzontidæ* Girard, Expl. and Surv. for R. R. Route to Pacific Ocean, X, Fishes, 376, 1858.

General distribution: Temperate regions in both the northern and southern hemispheres, anadromous or landlocked.

Body eel-shaped, subcylindrical anteriorly, compressed behind; the mouth nearly circular, suctorial, usually armed with horny teeth, or tooth-like tubercles which are simple or multicuspid, resting on papillæ; those

immediately above and those immediately below the œsophagus more or less specialized; eyes developed in the adult; gill-openings 7, arranged in a row along the sides of the "chest"; nostril on top of head just in front of the eyes; lips present, usually fringed; dorsal fin more or less deeply divided by a notch, the posterior part commonly continuous with the anal around the tail; intestines with a spiral valve; eggs small.

KEY TO THE SOUTH AMERICAN GENERA OF PETROMYZONIDÆ.

a. Supraoral lamina median and undivided; anus under the anterior part of the second dorsal; second dorsal fin distinct from the caudal.

b. Lingual teeth distinct and conic; supraoral lamina transversely extended, quadricuspid; infraoral crescent-like, sinuous or denticulate on the edge; discal teeth numerous and in divergent series. 1. *Geotria.*

bb. Lingual teeth three, standing on the same base, pointed and curved, the median smallest; discal teeth in concentric series, the outer containing the largest teeth, about 24 on each side. 2. *Exomegas.*

aa. Two lateral supraoral laminæ entirely separate, triangular, each with three conic teeth; infraoral lamina crescent-shaped, with about nine acute conical cusps; discal teeth in somewhat distant series, radiating from the center, those of a series more or less confluent; lingual teeth serrate, in two pairs; anus under the posterior part of the second dorsal; posterior dorsal continuous with the caudal. 3. *Caragola.*

1. GEOTRIA Gray.

(Plate XXX.)

> *Geotria* Gray, Proc. Zool. Soc. London, 1851, 238, pl. IV, fig. 3, and pl. V; id. List Spec. Fish. Brit. Mus. I, 142, pl. 1, fig. 3 and pl. 2, 1851 (*australis*).

> *Velasia* Gray, Proc. Zool. Soc. London, 1851, 239, pl. IV, fig. 4; id. List Spec. Fish. Brit. Mus. I, 143, pl. 1, fig. 4, 1851 (*chilensis*).

= *Velasia* Günther, Cat. Fish. Brit. Mus. V, 508, 1870; Gill, Proc. U. S. Nat. Mus. V, 524, 1882 (*chilensis*).

Macrophthalmia Plate, Sb. Ges. Naturf. Fr. Berlin, 1887, 137 (*chilensis*).

Type: *Geotria australis* Gray.

Distribution: Temperate regions of the southern hemisphere.

Distinguished from *Exomegas* by having distinct lingual teeth.

Plate distinguishes between the three species of this genus as follows:

a. Labial teeth numerous and close together.

b. Outer lingual tooth very large, with 2 large and 1 median short point on a low base; two small inconspicuous inner lingual teeth. Supraoral plate plainly denticulate; a small gular sack in the ripe ♀. Australia, New Zealand and South America. 1, *chilensis.*

bb. Outer lingual tooth with 3 uniform points; two larger, inner, lingual teeth each larger than the outer; supraoral plate smooth or denticulate; no gular sack. New Zealand, Tasmania. *stenostomus.*[1]

aa. Labial teeth wide apart; outer lingual tooth large with two large points on a high base; 2 inconspicuous lingual teeth; supraoral plate smooth or nearly smooth; an enormous gular sack even in immature specimens. Australia and South America. 2, *australis.*

1. Geotria chilensis (Gray).

(Plate XXX, Figs. 1 and 1*a*.)

Velasia chilensis Gray, Proc. Zool. Soc. London, 1851, 239, pl. iv, fig. 4 (Chili, in fresh water); id. List. Spec. Fish. Brit. Mus. 143, pl. i, fig. 4, 1851; id. Ann. & Mag. Nat. Hist., XIII, 63, 1854; Philippi, Wiegm. Arch. 1863, 207. pl. x, fig. a (Valdivia).

Geotria chilensis Günther, Cat. Fish. Brit. Mus., XIII, 509, 1870; Hutton, Trans. New Zealand Inst., V, 271, 1872 and XIII, 216, 1875; Eigenmann & Eigenmann, Proc. U. S. Nat. Mus., XIV, 24, 1891; Gill, Mem. Nat. Acad. Sci. Washington, VI, 110, 1893; Berg, An. Mus. Nac. Buenos Aires, IV, 122, 1895 (Rio de la Plata); Delfin, Catalogo de los Peces de Chile, 13, 1901. Plate, Zool. Jahrb. Suppl. V, 660, 1902 (Australia; New Zealand; Valdivia; Puerto Montt.).

Macrophthalmia chilensis Plate, Sb. Ges. Naturf. Fr. Berlin, Oct. 19, 1897, 137. (Source of the Rio Maullin from the Lago Llanquihui.)

Habitat: Streams of Chili and Argentina; New Zealand and Australia.

"Outer lobes of the maxillary dental lamina broad with a sharp convex edge, inner narrow and pointed; mandibular lamina crescent-shaped, with numerous obtuse points; suctorial teeth in numerous series, close together; a series of larger, broad, scale-like teeth round the mandibulary lamina; suctorial disk not dilated, circular; first and second dorsal fins widely separate from each other; back greenish; sides and abdomen silvery." Günther.

No specimens of this species were obtained by Hatcher, nor has it been actually reported from any of the streams of Patagonia. Its presence in New Zealand, Chili and La Plata makes its occurrence in Patagonian waters certain. The fact that it has not been taken is easily accounted for by its anadromic habit. So few specimens of the lampreys are known that nothing is definitely settled concerning the generic or specific identity. It is not improbable that Berg's *Geotria chilensis* is in reality an *Exomegas.*

[1] Plate XXX, fig. 2.

2. GEOTRIA AUSTRALIS Gray.

(Plate XXX, Figs. 3 and 3*a*.)

Geotria australis Gray, Proc. Zool. Soc. 1851, 238; id. List Spec. Fish Brit. Mus. 142, pl. ii; 1851 (Inkarpinki River); Günther, Cat. Fish. Brit. Mus. VIII, 508, 1870; Plate, Zool. Jahrb. Suppl. V. 668, 1902 (Valdivia, Chili; King George's sound, Australia).

Habitat: Australia and Chili.

No specimens of this species were obtained by Hatcher. The following is a description based on the type specimen.

"Skin of the throat very lax, forming a large pouch; maxillary lamina thin, crescent-shaped, with four sharp teeth, the middle pair of which are only half as broad as the outer. Mandibulary lamina very low, slightly sinuous; suctorial teeth in numerous series, rather distant from one another, aniscuspid; only those nearest to the mouth somewhat larger, the others small; only one transverse series of very small teeth between the mandibular lamina and the posterior lip, which is beset with numerous broad, leaf-like fringes, as in the remainder of the margins of the disk; suctorial disk subtriangular with the lateral lobes very broad; first and second dorsal fins rather widely separated from each other." Günther.

2. EXOMEGAS Gill.

Exomegas Gill, Proc. U. S. Nat. Mus., V, 524, 1882 (*macrostomus*).

Type: Petromyzon macrostomus Burmeister.

Günther (Cat. Fish. Brit. Mus. VIII, 505, 1870) was the first to recognize the aberrant nature of this genus. He says: "The following species would appear to be the type of a distinct genus, but it will be better to leave its creation to an ichthyologist who will be able to characterize it from an autopsy of examples." The genus was named by Gill, *l. c.* It is not improbable that it is synonymous with *Geotria*. Smitt says on this point:

"Cette structure de la ventouse et de la bouche, comparée aux descriptions et aux figures des *Geotria* et des *Velasia* chez les auteurs, ne nous donne aucun signe de divergence de forme mais bien de développement. C'est un plus-ou-moins du développement des cartilages et de la substance cornée du même type. Si l'on place les espèces décrites dans

l'ordre suivant: *Velasia chilensis*, *Geotria australis*, *Exomegas macrostomus*, et enfin notre exemplaire, on voit une série continue de développement de ce plus-ou-moins. Les termes de cette série, s'ils se trouvent constants à des différents locaux, peuvent naturellement être regardés comme des espèces distinctes ou des formes locales—c'est là une question de convenance—mais certainement ils ne méritent pas d'être des types génériques."

Larvæ very similar to those of *Petromyzon* but with more than 80 preanal myomeres; a triangular nasal opening; dentition simple, a lingual tooth with 3 points, of which the median is very small; suctorial teeth radially arranged, papillary; no median, supraoral or infraoral teeth; mouth bordered by cutaneous lamina; dorsals remote.

Distribution of the Species: Gallegos to Rio de la Plata.

a. Back rounded; a gular pouch. 3. *macrostomus.*

aa. Back with a flattened area bordered by two dermal folds, merged behind and continued in front on the snout; no gular pouch. 4. *macrostomus gallegensis.*

3. Exomegas macrostomus (Burmeister).

Petromyzon macrostomus Burmeister, Anal. Mus. Buenos Aires, 1868; Act. Soc. Paleont. XXXVI; Günther, Cat. Fish. Brit. Mus. VIII, 506, 1870.

Exomegas macrostomus Gill, Proc. U. S. Nat. Mus. V, 524, 1882; id. Science XXIII, 30, Jan. 19, 1894; id. Proc. U. S. Nat. Mus. XVII, 110, 1894.

Geotria macrostomus Berg, Anales del Museo de La Plata I, 2, plate 1, 1893 (Island of Flores, near Montevideo).

This species, if distinct from the variety *gallegensis*, is known from but two specimens; one, 40 cm. long, described by Burmeister was found alive in the Calle de Mexico in Buenos Aires in 1867, immediately after a heavy rain; the second, 44 cm. long, was obtained in 1890 and was recorded by Berg. If distinct from the Gallegos specimens, this species is extralimital.

"No teeth in the circumference of the mouth; outer row of the 10–11 concentric series largest, about 24 on each side; gular sack large." Berg.

4. EXOMEGAS MACROSTOMUS GALLEGENSIS (Smitt).

(Plate XXX, Figs. 4 and 4*a*.)

Geotria macrostoma gallegensis Smitt, Bihang Till K. Sv. Vet. Akad. Handl. Band 26, afd. iv, No. 13, 23 (Rio Gallegos and its tributaries, Rio Ruben and Rio Turbio).

This variety is known from a single adult individual and several larvæ. It differs from *macrostomus* chiefly in the flat dorsal region.

3. CARAGOLA Gray.

< *Caragola* Gray, Proc. Zool. Soc. London, 1851, 239, pl. iv, fig. 5; id. List Spec. Fish Brit. Mus., I, 143, pl. 1, fig. 5, 1851 ; Gill, Proc. U. S. Nat. Mus., V, 525, 1882 (*lapicida*).

<*Mordacia* Gray, Proc. Zool. Soc. London, 1851, 239, pl. iv, fig. 6; id. List Spec. Fish Brit. Mus., I, 143, pl. 1, fig. 6, 1851.

= *Mordacia* Günther, Cat. Fishes Brit. Mus., VIII, 8, 507, 1870; Plate, Zool. Jahrb. Suppl., V, 1902, 654.

Type: Caragola lapicida Gray.

This genus is considered but a subgenus of *Geotria* by Smitt, as a distinct genus by Günther, and the type of a distinct family by Gill.

Second dorsal continuous with the caudal; two pairs of serrated lingual teeth; maxillary dentition consisting of two triangular groups, each with three conical acute cusps.

Plate considers three species as valid which he distinguishes as follows:

a. Outer lingual tooth a broad transverse plate with numerous points; eyes small.

b. Wreath of inner labial teeth closed in the middle in front with three single pointed teeth. 5. *mordax*.

bb. Wreath of inner labial teeth closed in the middle in front with one single pointed tooth. 6. *lapicida*.

aa. Outer lingual tooth triangular, with but two retrorse hooks. Eyes relatively large. 7. *acutidens*.

5. CARAGOLA MORDAX (Richardson).

(Plate XXX, Fig. 5.)

Petromyzon mordax Richardson, Voy. Erebus and Terror, Fish., pl. 38, 1845 (Tasmania).

Mordacia mordax Gray, List Spec. Fish. Brit. Mus., 144, pl. 1, fig. 6, 1851 (copied); Günther, Cat. Brit. Mus., VIII, 507, 1870 (Valparaiso; Tas-

mania); Steindachner, Zool. Jahrb. Suppl., IV, 334, 1898 (Tumbes); Delfin, Catalogo de los Peces de Chile, 13, 1901 (Rio Tucapel and Puerto Montt); Plate, Zool. Jahrb. Suppl., V, 654, 1902 (Murray River).

Habitat: Coastwise streams of Chili, south to at least Puerto Montt (Tasmania).

"Mandibular lamina crescent-shaped, with about nine acute conical cusps, three of which are larger than the others; suctorial teeth in somewhat distant series, radiating from the center; the teeth of the series between the mandible and posterior lip as numerous as those of the other series but rather more confluent; anterior labial teeth converging and confluent behind, each tooth of the posterior pair like one half of an elongated oval; suctorial disk elliptic, with a free lip behind." Günther.

6. Caragola lapicida Gray.

(Plate XXX, Fig. 6.)

Caragola lapicida Gray, Proc. Zool. Soc., 1851, 239 (Valparaiso). List Spec. Fish Brit. Mus., 143, pl. I, fig. 5.
Mordacia lapicida Plate, l. c., 654 (Tumbes, Chili).
Petromyzon anwandteri Philippi, Wiegm. Arch. 1863, 207, tab. X, fig. *b* (Valdivia).
Habitat: Chili.

7. Caragola acutidens (Philippi).

(Plate XXX, Fig. 7.)

Petromyzon acutidens Philippi, Ann. & Mag. Nat. Hist., XVI, 1865, 221.[1]
Mordacia acutidens Plate, l. c. 657.
Habitat: Chili.

Class II. PISCES.

<Pisces Artedi; Genera Piscium 1738.
<Pisces Linnæus Sytema Naturæ ed. X, I, 239, 1758.
=Pisces Müller, Abhandl. K. Akad. Wiss. Berlin, 1844.

[1] This is the translation of an article credited to "Wiegm. Arch. 1864, 107." It is not found in the place cited.

Superorder OSTARIOPHYSI.

Ostariophysi Sagemehl, Morph. Jahrbuch X, 1–120, plates I and II.

Anterior four vertebræ coössified, much modified; frequently a chain of four ossicula auditus forming the Weberian apparatus attached to the anterior vertebræ and connecting the air-bladder with the auditory apparatus; air-bladder connected with the alimentary canal by a duct. Parietals separating the frontals from the supraoccipital or fused with the latter. Shoulder girdle suspended from the skull by a long post temporal; mesocoracoid arch well developed; opercle well developed. Ventrals abdominal, without spines.

The fishes belonging to the families making up the order or superorder of Ostariophysi are the dominant forms in the fresh waters of the world. They fall naturally into two groups or orders:

1. Nematognathi with no subopercle or symplectic bone; the supraoccipital and parietals coössified; the maxillary usually without teeth and reduced to form the core of a variously developed barbel; no scales.

II. Plectospondyli, a less solid group; with subopercle and symplectic bones and with a well formed maxillary and frequently with teeth.

Of these the Nematognathi are found both in the northern and southern hemispheres and have also become inhabitants of the sea.

The Plectospondyli fall into three groups of familes, those related to the *Cyprinidæ*, confined chiefly to the northern hemisphere but overflowing into northern Africa, those related to the *Characidæ* inhabiting Africa and South America but overflowing into Central America and Mexico, and those related to the *Gymnotidæ* and confined to tropical America.

Of the 1,200 or more species of fresh-water fishes recorded from tropical America, about 1,000 belong to the Ostariophysi; in round numbers about 500 of these belong to the Nematognathi and another 500 to the Plectospondyli. Of the African fresh-water fishes a much smaller per cent. are Ostariophysi.

Of this vast array of American species, very few are found within the boundaries of the region under consideration and most of these barely cross its northern border.

Order II. NEMATOGNATHI.

Nematognathi Gill, Fishes of East Coast, 1870.

The following opinions expressed several years ago in a then obscure and now extinct journal are still, in part, pertinent and are repeated with a few verbal changes.

Not many fossils of this order have been found, and those which have been discovered do not help us materially in determining the interrelations of the higher groups.

The date of the differentiation of the orders of the *Ostariophysi* is uncertain. Silurinæ, Bagarinæ and Pimelodinæ were separated as early as the beginning of the Tertiary, and as these subfamilies are quite remote from the most primitive living nematognathid, the Nematognathi must extend into the Secondary period.

The Nematognathi reach their highest development in the neo-tropics, where they constitute forty per cent. of the entire freshwater fish fauna. Most of the families, sub-families and genera now inhabiting this region have undoubtedly originated here. In most of the families the maxillary bone is a mere vestige and serves only as a support for a highly specialized dermal appendage, the maxillary barbel. So greatly has this been modified, even in its development, that Ryder seriously questioned whether the basal bone of the maxillary barbel in the North American cat-fishes is in reality the vestige of a maxillary. No doubt need, however, be entertained on that score, since in *Diplomyste* the basal bone of the short primitive maxillary barbel is a functional dentiferous maxillary.

The comparative development of the maxillary is, then, an excellent guide to the determination of the rank any family is to occupy in the system.

Other structures valuable in this respect are the different barbels so highly developed in some forms. Of the development of the barbels of *Ictalurus albidus*, Ryder says:

"The remarkably developed barbels of the embryos of the species make their appearance very early, especially the maxillary pair; these appear on the second day. . . . The barbels on the lower jaw do not appear till the fourth day of the development is completed. . . . The last of all to be developed is the nasal pair, . . . (which) does not appear until the seventh day."

In *Diplomyste* only short maxillary barbels are developed, and, as stated above, the maxillary is dentiferous and forms the mouth border above. It therefore has its barbels less specialized than the remaining families, while its maxillary is more generalized and resembles that of other fishes. The *Diplomystidæ* may therefore be considered the most primitive of the Nematognathi. At present this family is restricted to the fresh waters of central Chili and northern Patagonia.

The next important factor to be considered is the relative development and specialization of the air-bladder and Weberian apparatus. In the *Bunocephalidæ* and the *Siluridæ*, with the exception of the *Ageneiosinæ*, the air-bladder is large and lies below the coössified vertebræ. In the remaining South American families the air-bladder has been split into lateral halves, and, with the corresponding bones of the Weberian apparatus, has been enclosed in a bony capsule.

In the *Bunocephalidæ* there are no indications of any approach to the enclosed air-bladder, and indeed this family shows little resemblance to the remaining families. It was early differentiated from the descendants of the *Diplomystidæ*, but not before the maxillary had become quite vestigial. Two subfamilies have become differentiated ; they differ chiefly in the number of vertebræ in the tail and the number of anal rays. This family inhabits the La Plata basin, the Amazon and the South American rivers to the north of it.

The cosmopolitan family, *Siluridæ*, is composed of a large number of subfamilies, seven of which are American, or have representatives in America. They vary considerably from the most generalized Tachisurinæ, which most resemble the *Diplomystidæ*, to the Doradinæ and Ageneiosinæ, in which last we observe an approach to the conditions obtaining in the families with closed air-bladders.

As is intimated above, the Tachisurinæ are the lowest of the living *Siluridæ*. The members of this subfamily are mostly marine, and from it have, in all probability, been derived the remaining subfamilies. Some members of the Tachisurinæ have only the maxillary barbels developed, while in others the mental barbels have been added.

From the Tachisurinæ have unquestionably been derived the Callophysinæ and Pimelodinæ, which differ from each other in dentition. Both these subfamilies are neotropical in their distribution, the Callophysinæ being found in the Amazon and northward, the Pimelodinæ in the whole

region from the La Plata to Mexico. One of the chief features modified in passing from the Tachisurinæ to the Pimelodinæ is the space between the anterior and posterior nares. In the Pimelodinæ the barbels obtain their greatest specialization. The nasal barbels are, however, not developed before the Bagrinæ are reached, to which all the North American species belong.

From the Pimelodinæ have also been derived the Doradinæ, in which dermal ossifications first make their appearance, although minute plates are noticed along the anterior portion of the lateral line of *Platystomatichthys sturio* (Pimelodinæ).

In the Doradinæ and the succeeding subfamilies of *Siluridæ* the Weberian apparatus varies greatly and the whole group seems to be in a state of unstable equilibrium.

In the Ageneiosinæ appears for the first time the great reduction and splitting into lateral halves of the air-bladder. From the Ageneiosinæ were undoubtedly directly derived the Hypophthalmidæ.

From the primitive Ageneiosinæ and Auchenipterinæ have evidently been derived, as a lateral offshoot, the *Pygidiidæ*, of which the Cetopsinæ retain the most ancestral traits. In this family nasal barbels again appear. Some members of Stegophelinæ have lost the habit of free swimming and live as commensals or parasites in the gill-cavity of large species of the *Siluridæ*.

The three remaining families were, by Dr. Günther, united in one of his inferior groups, Hypostomatina. They have little external resemblance to the *Siluridæ*.

The *Callichthyidæ* have two series of smooth plates covering the sides, while the *Loricariidæ* have several series of rough plates. The teeth and dentiferous bones of the latter have also been considerably modified. The *Argidæ* are dwarfed forms inhabiting high mountain streams. They are naked but otherwise similar to the mailed *Loricariidæ*.

Family II. *DIPLOMYSTIDÆ*.

= *Diplomystidæ* Eigenmann, Zoe, Vol. I, 14, 1890.

Air-bladder well developed, simple or with transverse constrictions, lying free in the abdominal cavity. Mouth terminal, teeth incisor-like and villiform; intestines short, arranged in longitudinal folds. Body naked. Diaphragm membranaceous. Tip of scapular process touching basioccip-

ital. Dorsal short, confined to the abdominal portion of the vertebral column. Opercle well developed and movable; adipose fin present; occipital process not forming a bony bridge from the occipital to the dorsal plate. Caudal vertebræ not compressed, the neural spines simple, spine-like. Maxillary well developed, provided with teeth and forming the sides of the jaw; nares approximated; gill membranes somewhat joined, but free from the isthmus. A single genus.

4. DIPLOMYSTE.

Diplomyste Dumeril, Ichthyol. Analyt., 487, 1856 (*papillosus*).
Diplomystes Bleeker, Nederl. Tijdschr. Dierkunde, I, 92, 1863 (*papillosus*).
Diplomystax Günther, Cat. Fish. Brit. Mus., V, 180, 1864 (*papillosus*).

The distinctive character of this genus is the development of the maxillary bone. It forms the sides of the mouth and carries a very narrow band of teeth. No mental barbels; maxillary barbels thick, compressed at the base. Occipital process not visible externally; no bony orbit. Skull with two nearly parallel median ridges above. Fontanel extending to the base of the occipital process, with a rather broad interruption behind the eyes. A single species.

Habitat: Chili, near Valparaiso and Santiago.

8. Diplomyste papillosus (Cuvier & Valenciennes).

(Plate XXXI, Figs. 1, 1*a* and 1*b*.)

Molina "Hist. Nat. Chile, 199, No. 9."
?? *Silurus chilensis* Linnæus, Syst. Nat. Ed. XIII, 1359, 1788 (Chili).
?? *Pimelodus chilensis* Lacépède, Hist. Nat. Poiss., V, 114, 1803 (Freshwaters of Chili).
Arius papillosus Cuv. & Val. Hist. Nat. Poiss., XV, 118, pl. 431, 1840 (Valparaiso; Santiago); Gay, Hist. Chile, II, 305, pl. fig. 1, 1848 (Chili) Philippi, MB. Ak. Wiss. Berlin, 1866, 710 (Chili).
Diplomystax papillosus Günther, Cat. Fish. Brit. Mus., V, 180, 1864 (Chili).
Diplomystes papillosus Eigenmann & Eigenmann, Proc. Cal. Acad. 2d ser. vol. I, 1888, 149 (Rivers of Santiago).
Arius carcharias "Leybold, Anales de la Universidad de Chili, 1859 (Chile)"; Philippi, MB. Akad. Wiss. Berlin, 1866, 711 (Chili).

Arius villosus Philippi, l. c., 712 (Santiago).
Arius squalus Philippi, l. c., 713 (Santiago).
Arius micropterus Philippi, l. c., 713 (Santiago).
Arius synodon Philippi, l. c., 713 (Santiago).

Habitat: Central portion of Chili.

The numerous species of Philippi seem to be based on individual differences. The seventh dorsal ray is always divided to near its base, and in one of the specimens examined by me there are eight dorsal rays.

Slender, terete forward, compressed toward the tail; the width, below the dorsal spine, equals the depth. Head short and blunt, somewhat pointed in young, the profile strongly decurved in front; head entirely covered with a layer of muscle and skin, the surface of the bones irregular, rugose, the interorbital portion flattish, postorbital portion with two nearly parallel median ridges, fontanel between the two median ridges, extending from the occipital process to in front of the eyes, with a broad bridge behind the eyes. Occipital process a deep but short crest.

Eye small, circular, 3 in snout, little more than 1 in the interorbital, 3 in the interocular, 7_2 in the head.

Nostrils close together, with a membrane around the entire margin forming an 8-shaped figure, the portion of the membrane separating the nasal openings highest.

Maxillary barbel broad and flattened at its base, scarcely reaching the base of the pectoral.

Snout sometimes long and pointed, usually rounded, projecting considerably beyond the lower jaw. Lips thick and strongly papillose. Maxillary bones reaching to below the eye, $2\frac{2}{3}$ in the head. The anterior half of the maxillary consists of a slender peduncle bearing two series of teeth; the posterior portion is flattened and about three times as wide as the anterior portion. Premaxillaries with a crescent-shaped patch of teeth, the outer four or five series compressed, incisor-like; teeth of the inner series very much smaller, not incisor-like. Vomer with two oval patches of large conical teeth, the patches becoming united with age. Teeth of the lower jaw compressed, incisor-like; the band deep in front tapering rapidly to the rictus.

Gill-membranes usually separate to below the eye, entirely free from the isthmus. Gill-rakers $5 + 8$. Pseudobranchiæ well developed, not covered by a membrane.

Skin covered with minute cirri or papillæ, which are especially conspicuous over the humeral region and head, the tail sometimes smooth.

Distance of dorsal fin from tip of snout $2\frac{3}{5}$–$2\frac{4}{5}$ in the length, the spine stout and smooth, $1\frac{1}{2}$–$1\frac{2}{3}$ in head. Distance of the adipose fin behind the dorsal about equal to the length of the adipose fin or one-half longer, 5–6 in the length.

Caudal emarginate, with numerous, short, accessory basal rays.

Free margin of the anal straight or slightly convex, the fifth ray highest, about $1\frac{1}{2}$ in the head, rapidly decreasing to the last ray, which is about half the height of the fifth.

Pectoral spine very strong and with a leathery prolongation; height of the spinous portion $1\frac{2}{3}$–2 in the head; outer margin of the spine smooth, inner margin with strong, recurved teeth along its entire length.

Bases of all the fins, lower part of head, suborbital regions and opercles and a median line on the back purplish; rest of body and fins yellowish and under the lens dark.

Head 4–$4\frac{1}{2}$; depth $4\frac{1}{4}$–$5\frac{1}{2}$; Br. 7; D. I, 7 or 8; A. 9–12.

No specimens were collected by Hatcher and the above description is based on the material in the Museum of Comparative Zoölogy at Harvard University.

Family III. *PYGIDIIDÆ.*

>*Siluroidei trichomycteriformes* Bleeker, Nederl. Tijdschr. Dierk. I, 112, 1863.

>*Siluridæ opisthopteræ* Günther, Cat. Fish. Brit. Mus. V, 4, 1864.

>*Siluridæ branchicolæ* Günther, l. c.

>*Trichomycteridæ* Gill, Arrangement of Families of Fishes, 19, 1872.

=*Pygidiidæ* Eigenmann & Eigenmann, Am. Nat. July, 1888, and South Amer. Nematognathi 316, 1890.

Distribution of the species: East and west slopes from Colombia to La Plata and along the Andes to Patagonia.

Air-bladder vestigial, part on either side of the coalesced vertebræ and enclosed in a capsule formed by the lateral processes of the coalesced vertebræ only; the external orifice of the air-bladder capsule as in *Hypophthalmidæ*, its anterior side closed. Adipose fin none; dorsal usually on the caudal, sometimes on the abdominal portion of the vertebral column; anal short. Derm naked. Dorsal and pectoral spines scarcely developed.

But three genera of this family are known to occur within the limits of the area under consideration; they are *Nematogenys*, *Hatcheria* and *Pygidium*. Their relationship will be seen from the following key to all the genera of the family.

a. Dorsal entirely in front of the ventrals; vomer with teeth; head compressed; anterior nares almost labial. Gill-membrane broadly united with the isthmus. Eye almost entirely concealed under the skin. A single maxillary barbel; two pairs of mental barbels. Opercles unarmed. (*Cetopsinæ.*)

b. Teeth all conical or incisor-like, those on the vomer in a single series. *Hemicetopsis* Bleeker.

bb. Teeth on the premaxillary villiform, in a band, those on the vomer and on the mandible incisor-like, in a single series. *Cetopsis* Agassiz.

bbb. Teeth on the premaxillary and on the mandible villiform, in bands, those on the vomer in a single series. *Pseudocetopsis* Bleeker.

bbbb. Teeth all villiform, in bands. *Paracetopsis* Eigenmann & Bean.

aa. Dorsal above or behind the ventrals; no teeth on the vomer.

c. Gill-openings broad, the gill-membranes almost free or forming a free membrane across the isthmus. (*Pygidiinæ.*)

d. Anal short; eyes superior; mouth terminal; gill-membranes free or almost free from the isthmus.

e. Ventrals present.

f. A single maxillary barbel; opercles and preopercle unarmed.

g. Nasal barbels present; dorsal placed over the ventrals; one pair of mental barbels. *Nematogenys* Girard.

gg. Nasal barbels obsolete; dorsal placed behind the ventrals; two pairs of mental barbels. *Pariolius* Cope.

ff. Two maxillary barbels; opercle and preopercle with osseous prickles; nasal barbels present.

h. Caudal peduncle broad; caudal with numerous accessory rays. *Pygidium* Meyen.

hh. Caudal peduncle slender; caudal with very few accessory rays; dorsal emarginate. *Hatcheria* Eigenmann.

ee. Ventral fins none; otherwise like *Pygidium*. *Eremophilus* Humboldt.

dd. Anal long, partly in front of the dorsal; head greatly depressed; eyes infringing on the upper and lower surfaces of the head; mouth inferior; gill-membranes broadly joined to each other, free from the isthmus; opercle and preopercle with osseous prickles; a series of fine labial teeth. *Tridens* Eigenmann & Eigenmann.

cc. Gill-membranes confluent with the skin of the isthmus, the gill-opening a narrow slit in front of the pectoral; opercle and preopercle armed with spines; vent far behind the middle of the body; anal short. (*Stegophilinæ.*)

i. Upper lip with several series of numerous small, movable teeth; each jaw with several series of minute teeth; mouth inferior.

j. Gill-membranes broadly united with the isthmus.

k. Caudal widely forked, the upper lobe produced in a filament; a single maxillary barbel. *Pseudostegophilus* Eigenmann & Eigenmann.

kk. Caudal emarginate.

l. A single maxillary barbel. *Henonema* Eigenmann.

ll. Two maxillary barbels. *Homodiætus* Eigenmann.

kkk. Caudal rounded.

m. A single maxillary barbel. *Stegophilus* Reinhardt.

mm. Two maxillary barbels. *Miuroglanis* Eigenmann & Eigenmann.

jj. "Rimae branchiales confluentes, membrana branchiostega cum isthmo gulare haud connexa;" caudal rounded; maxillary barbel single; no accessory caudal rays. *Acanthopoma* Lütken.

ii. No labial teeth; teeth in the jaws in a single series.

n. Teeth pointed, in a single series in the intermaxillaries only; mouth sub-inferior; a single maxillary barbel. *Vandellia* Cuvier & Valenciennes.

nn. Teeth broad, incisor-like in both jaws; caudal forked; two maxillary barbels. *Pareiodon* Kner.

5. NEMATOGENYS Girard.

Nematogenys Girard, Proc. Acad. Nat. Sci. Phila., VII, 1854, 198 (*inermis*).

Type: Trichomycterus inermis Guichenot.

Dorsal fin placed over the ventrals, without a spine. Fontanel extending to base of occipital process, interrupted above the posterior margin of orbit. Opercle and preopercle unarmed. A single barbel on each maxillary and one pair of mental barbels.

Habitat: Central Chili.

9. NEMATOGENYS INERMIS (Guichenot).

(Plate XXXI, Fig. 2, and Plate XXXII, Fig. 2.)

Trichomycterus inermis Guichenot, in Gay Hist. Chile Zool., II, 312, pl. ix, fig. 2, 1848 (Chili).

Nematogenys inermis Girard, Proc. Acad. Nat. Sci. Phila., VII, 1854, 198; id. U. S. Naval & Astron. Exped. 240, pl. xxxii, 1855 (Rio de Maypu near Santiago); Philippi, MB. Ak. Berl., 716, 1866 (Chili); Günther, Cat., V, 272, 1864 (copied); E. & E. Proc. Cal. Acad. Sci., 2d Ser., II, 50, 1889 (Curico; Santiago); id. South Am. Nematognathi, 322, 1890 (Curico; Santiago).

Nematogenys nigricans Philippi, *l. c.*, 716 (Chili).

Nematogenys pallidus Philippi, *l. c.*, 716 (Chili).

Habitat: Fresh waters of Central Chili.

N. nigricans and *pallidus* seem to be color varieties of *N. inermis.*

Tail compressed, head depressed, the caudal peduncle about as deep as the body. Head entirely covered with soft skin, little longer than wide, its depth $1\frac{3}{5}$–2 in its length. Eye small, superior; interocular width little less than length of snout; orbit without a free margin. Mouth wide, terminal, each jaw with a rather deep band of villiform teeth.

Gill-membranes narrowly joined to the isthmus.

Anterior nasal opening with a barbel which is about $1\frac{1}{2}$ times as long as the eye; a series of pores extending from it backward below the eye; a prominent pair of pores between the eyes.

Pectoral pore minute, above and behind the pectoral spine.

Origin of dorsal fin one-fifth nearer tip of snout than to base of middle caudal rays in specimens .12 meter long, one-fifth nearer base of caudal rays than to tip of snout in a specimen .26 meter long.

Margin of all the fins rounded. Caudal with numerous accessory rays, the middle caudal rays 1–$1\frac{1}{3}$ in the head. Origin of ventrals below or slightly behind the first dorsal ray. Inner margin of pectoral spine serrate, its lower surface spiny.

Light brown mottled with darker, a series of about 5 light areas along the lateral line; fins speckled.

Head $4\frac{1}{3}$–$3\frac{4}{5}$; depth 7–6; D. 10; A. 11; Br. 10–12.

This species does not belong to the tropical American fauna. Nor can it technically be referred to the Patagonian fauna, since no specimens have been recorded south of Central Chili. It occupies intermediate ground and possibly touches the Patagonian region on its northwestern frontier.

This account is based on material in the Museum of Comparative Zoölogy.[1]

[1] PYGIDIUM Meyen.

Trichomycterus Valenciennes, Humboldt, Rec. d'Obs. Zool. et Anat. II, 348, 1833 (*nigricans*) not *Thrichomycterus* Humboldt.

Thrychomycterus Cuv. & Val. XVIII, 485, 1846 (misquoted).

Thrichomycterus Girard, Proc. Acad. Nat. Sci. Phila., VII, 1854, 198; Girard, U. S. Nav Astron. Exped. II, 242, 1855 (misquoted).

Pygidium Meyen, Reise, I, 475, 1835 (*fuscum*).

Type: Pygidium fuscum Meyen.

Habitat: Andes from Central Chili to Colombia; Callao Bay; Amazon to Cudajas; Southeastern Brazil; Central Argentine Republic.

The reasons for using the name *Pygidium* instead of the older *Trichomycterus* were given by Eigenmann & Eigenmann, S. A. Nematognathi, 325. Inasmuch as some naturalists still persist in using the name *Trichomycterus*, the statement made by us may be repeated:

6. HATCHERIA Eigenmann gen. nov.

Type: Hatcheria patagoniensis sp. nov.

Dorsal long, emarginate; caudal with very few accessory rays, which are graduated; anal below the posterior half of the dorsal; caudal peduncle very slender; caudal emarginate, the lobes rounded.

SPECIES OF HATCHERIA.

a. D. 21; origin of dorsal equidistant from occiput and tip of caudal; anal inserted below the ninth dorsal ray and terminating under the seventeenth; ventrals extending to vent. 10. *macræi.*

aa. D. 15; origin of dorsal equidistant from tip of snout and tip of caudal; last ray of anal under last ray of dorsal; distance of anal from base of caudal $3\frac{3}{4}$ in the length. 11. *maculata.*

aaa. D. 15; origin of dorsal equidistant from tip of caudal and posterior nares; gill openings not extending forward to eye; last anal ray under last dorsal ray; distance of anal from base of caudal about $4\frac{1}{2}$ in the length. 12. *patagoniensis.*

aaaa. D. 14; origin of dorsal equidistant from tip of caudal and occiput, its last ray over fourth ray of anal; gill openings extending forward to below eye, the membrane free from the isthmus; distance of anal from base of caudal 5 in the length. 13. *areolata.*

10. HATCHERIA MACRÆI (Girard).

(Plate XXXII, Figs 1, 1*a* and 1*b*.)

Thricomycterus macræi Girard, U. S. Naval and Astronomical Expedition 245, 1855 (Uspullata, elevation, 7000 feet).

The only claim for retention the name *Trichomycterus* possesses is its distinctiveness from *Thrichomycterus* Humb. = *Eremophilus* Humboldt. Twenty-two years before any species of *Trichomycterus* Val. was known, the name *Thrichomycterus* was proposed by Humboldt as an alternative for his *Eremophilus*, if future investigations should prove *Eremophilus* to be objectionable. Upon proposing the name *Trichomycterus* Valenciennes states: "Nous prenons pour le nouveau genre le nom de *Trichomycterus* imaginé par M. de Humboldt," so the names can hardly be considered distinct, being either a misprint or a lapsus digiti. Valenciennes afterwards misquotes himself, spelling the name *Thrychomycterus* instead of *Trichomycterus*. Girard also misquotes Valenciennes or quotes Humboldt correctly, using *Thrichomycterus* instead of *Trichomycterus*.

This genus has a wide distribution, extending along the Andes from Caracas to Chili on both slopes. It is distinctly a mountain form, but it descends the Pacific slope to the coast at Callao and the Amazon to Cudajas. It further occurs in the highlands of Guiana and Eastern Brazil. There are in all about 35 species known. Some of these are found on both sides of the Andes, but none have a wide distribution. On the contrary, the species seem to be local differentiations of this widely distributed genus. Contrary to the general rule of distribution of South American fresh-water fishes, that a genus with many species and a wide distribution has many representatives in certain favorable localities, there is no place on record harboring more than one species of this genus. We may expect the finding of many other species as restricted basins or isolated valleys of the Andes and the temperate portions of South America are explored.

The genus is without doubt one of very long standing. In Central Chili and Patagonia it has become differentiated into *Hatcheria*.

Pygidium macræi Eigenmann & Eigenmann, Proc. Cal. Acad. Sci. 2d ser., II, 51, 1889 (Uspullatuo); id., South Am. Nematognathi 328, 1890 (Uspullatuo).

Elongate, rather compressd, especially backward. Head as broad as long, snout rounded; eye small, midway between tip of snout and end of opercle; none of the barbels reaching the gill-opening.

Gill-opening scarcely continued forward, joined to the isthmus for a distance equal to half the width of the mouth.

Pectorals obliquely truncate, the first ray not produced; origin of dorsal some distance behind ventrals, equidistant from occiput and tip of caudal; fourth or fifth dorsal ray highest, then gradually decreasing in height to the last. Caudal emarginate, the upper lobe pointed, the lower rounded; anal inserted below the 9th dorsal ray and terminating under the 17th; ventrals inserted nearer tip of snout than to tips of middle caudal rays, reaching to the vent. Head $6\frac{1}{5}$ (7 in the total); depth 6; D. 21. A. 10.

This account is drawn from a specimen (No. 8298) in the Museum of Comparative Zoölogy. It came from Uspullatuo and is probably the type of the species.

11. Hatcheria maculata (Cuvier & Valenciennes).

(Plate XXXIII, Figs. 1, 1*a* and 1*b*.)

Trichomycterus maculatus Cuvier & Valenciennes, Hist. Nat. Poiss., XVIII, 493, 1846 (Santiago); Guichenot in Gay, Hist. Chile Zool., II, 311, 1848 (Chili); Günther, Cat. Fish. Brit. Mus. V, 273, 1864; Girard, Proc. Acad. Nat. Sci. Phila., VII, 1854, 199 (Mapocho); Philippi, Mb. Akad. Wiss. Berl. 1866, 716; Delfin, Catalogo de los Pesces de Chile, 30, 1901.

Thrichomycterus maculatus Girard, in part, U. S. Naval and Astronomical Expedition 243, 1855 (Rio Mapocho).

Pygidium maculatum Eigenmann & Eigenmann, Proc. Cal. Acad. Sci. 2d ser., II, 51, 1889 (Rio Mapocho); id., South Am. Nematognathi 329, 1890 (Rio Mapocho).

Elongate, somewhat compressed; head as long as wide; caudal peduncle long and slender. Eye small, midway between tip of snout and end of opercle. Lips and lower surfaces of the head thickly covered with

warts. Gill-openings not continued forward to below the eye, the membranes joined to the isthmus for a distance equal to one-third the width of the mouth.

Pectorals rounded, the first ray not produced; origin of dorsal in front of the vent, but some distance behind the ventrals, equidistant from tip of snout and tip of caudal, its last ray over the last ray of the anal. Caudal long, truncate. Anal short and high, its height about equal to the length of the caudal, its distance from the base of the caudal $3\frac{3}{4}$ in the length. Origin of the ventrals equidistant from tip of snout and base of caudal, their tips reaching beyond the vent.

Back and sides marbled with light and dark brown; fins pale, immaculate.

Head $5\frac{1}{3}$ ($6\frac{1}{4}$ in the total); depth $7\frac{1}{2}$; D. 15; A. 9. This account is based on a specimen in the Museum of Comparative Zoölogy.

12. HATCHERIA PATAGONIENSIS Eigenmann sp. nov.

(Plate XXXIII, Fig. 2; and Plate XXXIV, Figs. 1 and 1*a*.)

Type: A specimen 118 mm. long. Rio Blanco, base of Andes. Lat. 47° 30′ S.; long. 72° W. Hatcher, collector.

Cotypes, 8 specimens, 96–113 mm.

Elongate, slender; head, 5; depth 8; caudal peduncle slender, its depth nearly 3, in the head, about 4 in its length; upper maxillary barbel reaching pectoral, lower to margin of interopercle, a broad lobe of skin joining base of lower maxillary barbel to the lower lip; snout pointed, mouth narrow, its width $3\frac{1}{2}$ in head, equal to interorbital; nasal barbels reaching beyond eye; width of head but little less than its length; greatest width of body behind the pectorals, 1.6 in the length of the head. Gill opening not extending forward to below eye; origin of dorsal equidistant from tip of caudal and posterior nares; base of dorsal equal to its distance from the caudal, its free surface emarginate, the anterior lobe rounded, the posterior pointed; beginning of last third of dorsal not much more than half as high as anterior lobe. Caudal moderate, emarginate, its lobes rounded, .8 of the length of the head. Anal broadly rounded, its last ray about under last ray of dorsal. Ventrals broad, their middle under origin of dorsal, $1\frac{1}{2}$ in head, equal to height of anal. Base of pectoral horizontal, closing edgewise to body, its lower part folded when appressed;

first ray sickle-shaped, slightly prolonged. Dark yellowish, more or less regularly spotted with darker, dorsal and caudal and pectorals irregularly blotched with black. D. (13) 15; A. 6.

Some of the cotypes are more robust in body; in one the anal is blotched like the caudal; in some the spots form regular series along the sides leaving lighter stripes between them.

13. Hatcheria areolata (Cuvier & Valenciennes).

(Plate XXXIV, Fig. 2.)

Trichomycterus areolatus Cuvier & Valenciennes, Hist. Nat. Poiss., XVIII, 492, 1846 (Coast of Chili); Guichenot, in Gay Hist. Chile, Zool., II, 309, 1848; Günther, Cat. Fish. Brit. Mus., V, 274; Delfin, Catalogo de los Peces de Chile, 30, 1901; Philippi, Mb. Akad. Wiss. Berlin, 1866, 714.

Pygidium areolatum Eigenmann & Eigenmann, Proc. Cal. Acad. Sci., 2d ser., II, 51, 1889 (Rio Mapocho); id. South American Nematognathi, 330, 1890 (Mapocho); Berg, An. Mus. Nac. Buenos Aires, IV, 143, 1895 (Coidola); Evermann & Kendall, Proc. U. S. Nat. Mus. XXXI, 86, 1906 (Rio Comajo; tributary of Lake Traful; tributary of Rio Limay).

Thrichomycterus maculatus Girard, in part, U. S. Naval and Astronomical Expedition 243, 1855 (Mapocho).

Elongate, subterete. Lips and lower surfaces of head thickly covered with small warts. Gill-openings continued forward to below the eye, the membranes free from the isthmus. Upper maxillary barbels reaching to the pectorals. Pectorals rounded, the first ray not prolonged; origin of dorsal slightly in front of the vent, equidistant from tip of caudal and occiput, its last ray over the fourth ray of the anal. Caudal very slightly emarginate. Distance of anal from the base of the caudal 5 in the length. Origin of the ventrals equidistant between tip of snout and middle of caudal; tips of the ventrals not reaching the vent.

Light brown, with purple longitudinal streaks.

Head $5\frac{3}{4}$ ($6\frac{2}{5}$ in the total); depth $8\frac{1}{2}$; D. 14; A. 8.

Based on a specimen in the Museum of Comparative Zoölogy.

Order III. PLECTOSPONDYLI.

Cope, Am. Assoc. Adv. Science, Indianapolis, 1871, 332.

As stated ante, p. 238, this order falls naturally into three groups of families which are considered suborders and distinguished as follows:

a. Lower pharyngeals falciform, parallel with the gill arches, usually provided with teeth; mouth more or less protracted, usually bordered by the premaxillaries only; jaws toothless; brain case produced between the orbits; basis cranii simple; no adipose. *Eventognathi.*

aa. Lower pharyngeals normal; mouth not protracted; teeth in the jaws or none; brain case usually not produced between the orbits; basis cranii double.

b. Not eel-shaped; vent submedian; a dorsal fin and usually an adipose dorsal; ventrals abdominal; mouth usually bordered by the premaxillary and maxillary, more rarely by the premaxillary only. *Heterognathi.*

bb. Eel-shaped; vent under the head or at throat; dorsal obsolete; ventrals wanting. *Gymnonoti.*

Of these suborders the Eventognathi belong to the northern hemisphere, not a single species having reached South America through natural channels.

The Gymnonoti are exclusively South American, reaching from Guatemala to La Plata. No species approach the Patagonian region.

Suborder HETEROGNATHI.

The *Heterognathi* are composed of one, possibly two families, the *Erythrinidæ*, peculiar to South America and the *Characidæ*, in South America and tropical Africa. The *Erythrinidæ* are not known to extend south of Buenos Aires.

Family IV. *CHARACIDÆ.*

Characini, Müller, Archiv Naturgesch., 9, Jahrg., I, 323, 1843.
Characinidæ, Richardson, Encycl. Brit., 8th ed., XII, 245, 1856.
Characinidæ, Günther, Cat. Fish, Brit. Mus. V, 278, 1864.
Characidæ, Gill, Mem. Nat. Acad. Sci. VI, 131, 1893.

The *Characidæ* flourish in the tropical fresh-waters; but one species reaches as far north as the boundary of the United States. Of the *Characidæ* inhabiting the fresh-waters of tropical America, numbering about 100 genera and nearly 500 species, only two reach with certainty the region under consideration. Both of these belong to the *Tetragonopterinæ*.

A third one is recorded from south of Buenos Aires without a distinct locality.[1] It is without scales and forms a distinct subfamily closely allied to the *Tetragonopterinæ*.

The relation of the Patagonian forms to those of other regions is shown by the following keys to the subfamilies of *Characidæ* and to the genera of *Tetragonopterinæ*.

SUBFAMILIES OF CHARACIDÆ.[2]

a. Teeth none; an adipose fin.
  b. Gill-rakers none; intestine very long. I. *Curimatinæ*, American.
  bb. Gill-rakers long, clupeiform; fourth gill arch with raker-like organs behind. II. *Anodinæ*, American.
aa. Teeth minute, mostly depressible; nares close together; gape short, mouth usually small; an adipose fin.
  c. Last gill-arch normal.
    d. Jaws well developed, the mandibles firm; teeth more or less spatulate, more or less firmly joined to the jaws; dorsal variable.
      e. Scales cycloid; teeth serrate or spoon-shaped; gill-membranes free from isthmus and from each other; no predorsal spine. III. *Hemiodontinæ*, American.
      ee. Scales ctenoid.
        f. Gill-membranes free from the isthmus. IV. *Neolebiinæ*, African.
        ff. Gill-membranes joined to the isthmus. V. *Distichodontinæ*, African.
    dd. Jaws very weak, mandibles transverse; teeth on the margins of fleshy lips, freely movable, spatulate; mouth subterminal, broad; dorsal short; gill-membranes joined to isthmus; a movable, procumbent, predorsal spine. VI. *Prochilodinæ*, American.
  cc. Last gill-arch modified.

[1] GYMNOCHARACINUS Steindachner.

(Plate XXXIV, Figs. 3 and 3*a*.)

Gymnocharacinus Steindachner, SB. Akad. Wiss. Wien, CXII, 20, 1903 (type *bergii*).

This genus differs from all other *Characins* in being naked.

GYMNOCHARACINUS BERGII Steindachner.

Gymnocharacinus bergii Steindachner, SB. Akad. Wiss. Wien, CXII, 20, 1903. (A brook from southern Argentina, exact locality not given.)

Head 4; depth 3⅔; D. 11; A. 13; V. 6–7. Snout blunt, jaws equal; maxillary not reaching to middle of eye; width of head 1.5 in its length; eye 4 in head; interorbital nearly 3; base of dorsal 2.4 in the head, its height 1.75; ventrals 2.4; base of anal less than twice in head; brown, a dark brown lateral band from the head to the caudal.

[2] The African genera are interpolated here although they very probably underwent a separate evolution and their position in the key does not represent their relationship.

g. Dorsal short; lower jaw composed of three elements; teeth minute, in a single series; gill-membranes grown to the isthmus; lower jaw with a longitudinal extent; premaxillary rudimentary. VII. *Chilodinæ*, American.

gg. Dorsal elongate, with 17–23 rays; fourth gill arch with an accessory respiratory organ; lower jaw composed of two elements; teeth minute, ciliform, in a single series in each jaw; anterior air bladder partly enclosed in a bony capsule. VIII. *Citharininæ*, African.

aaa. Teeth well developed, fixed in the jaws; an adipose fin or none.

h. Maxillary not rudimentary, not ankylosed with the premaxillary; premaxillaries not coössified; teeth compressed, truncate, notched, denticulate or serrate; sometimes canines also present. (See also *Bramocharax*.) Alimentary canal short.

i. Belly rounded before the ventrals; teeth truncate, notched or serrate.

j. No scales; no adipose; teeth in premaxillary in two rows, in maxillary and mandible in single series, narrow at base, broad at tip, 3–5 pointed; a long fontanel in occiput. IX. *Gymnocharacininæ*, south of Buenos Aires.

jj. Body fully scaled.

k. Skull with a parietal, and usually in the American genera, with a frontal fontanel; teeth in the lower jaw not in two complete series.

l. Premaxillary and mandible with a single series of teeth.

m. Dorsal with 11 rays or fewer.

n. Large frontal and parietal fontanels. Gill-membranes united, usually joined to the isthmus, free from it in some genera; intestine short; mouth small with little or no lateral extent; nares close together or remote. X. *Anostomatinæ*, American.

nn. No frontal fontanel, parietal fontanel if present confined to the occipital region. Gill-membranes sometimes slightly united, usually free from each other and from the isthmus; nares remote; mouth minute; adipose present or absent; no teeth on maxillary. XI. *Nannostomatinæ*, American.

nnn. Gill-membranes free from the isthmus and from each other; nares close together, separated by a flap only; fontanels large, separating the parietals and the frontals to at least the middle of the eye; adipose always present; maxillary with teeth. XII. *Aphiocharacinæ*, American.

mm. Dorsal with 15 rays. XIII. *Crenuchinæ*, American.

ll. Premaxillary with two or more series of teeth; nares approximate.

o. Gill-membranes united, free from isthmus; a single series of teeth in the lower jaw. XIV. *Iguanodectinæ*, American.

oo. Gill-membranes free from each other and from the isthmus.

p. Opercle prolonged; premaxillary with two, mandible with a single series of teeth; belly not keeled; gill-membranes free from isthmus; rakers close together.

q. Adipose fin present; no rakers on lower limb of anterior gill-arch; anal long (31); dorsal in part in front of anal. XV. *Diapominæ*, Rio Grande do Sul.

qq. No adipose; dorsal over anal, higher than long; anal long (20–31). XVI. *Stevardiinæ*, Trinidad.

pp. Opercle not prolonged; usually a single series of teeth in the lower jaw, some genera imperfectly with two series. XVII. *Tetragonopterinæ*, American and African.

kk. Skull without fontanels; mandible with two series of teeth.

r. An adipose dorsal; walls of the air-bladder not cellular. XVIII. *Piabucininæ*, American.

rr. No adipose fin; walls of the anterior portion of the posterior air bladder cellular; premaxillary, maxillary, and outer series of the teeth of the dentary tricuspid. XIX. *Lebiasininæ*, Pacific slope of Peru to Colombia.

ii. Belly compressed before the ventrals; no ventral spines; intestine short; gill-rakers moderate; nares close together.

s. Pectorals large, nearly or quite reaching anal, placed high or moderately so; gill-membranes free; breast more or less expanded. XX. *Gasteropelicinæ*, American.

ss. Pectoral small, placed low.

t. Body elongate; anal basis nearly horizontal. XXI. *Agoniatinæ*, American.

tt. Body deep; anal basis very oblique; mouth very oblique; pectorals on a level with or below the level of the lower margin of the preopercle. XXII. *Stethaprioninæ*, American.

iii. Belly trenchant and serrate, at least behind the ventrals; intestine short; body compressed and deep.

u. All teeth in the jaws in a single series, trenchant or serrate; gill-rakers mostly short. XXIII. *Serrasalmoninæ*, American.

uu. Premaxillary teeth in two series, teeth tricuspid or truncate; gill-rakers various. XXIV. *Mylinæ*, American.

hh. The minute maxillary ankylosed with the premaxillary.

v. Premaxillaries coössified; dentaries coössified; teeth conical or compressed, uni-, bi-, or tricuspid; lateral line along middle of body; alimentary canal short; nares close together; scales ctenoid.

w. Fontanel minute or absent; maxillary bordering the mouth. XXV. *Phaginæ*, African.

ww. A large fontanel separating the parietals and frontals to the eyes; maxillary not bordering the mouth; snout prolonged. XXVI. *Ichthyoborinæ*, African.

vv. Premaxillaries not coössified; maxillary in part bordering mouth, its posterior, toothless portion meeting the toothed part at an angle, snout not much prolonged; a few large triangular teeth in each jaw, nares close together; lateral line below the middle of body; fontanel separating the parietals and sometimes in part the frontals. XXVII. *Hydrocyoninæ*, African.

hhh. Premaxillaries not coössified; maxillary not rudimentary, not ankylosed with the premaxillary; the teeth conical or compressed (see *Bramocharax*); nares close together; gill-membranes free from isthmus; alimentary canal short.

x. Fontanel present.

y. Belly compressed; body long and narrow, knife-like anal long; teeth unequal; a pair of large canines in the lower jaw in front, received in two grooves in the palate; palate with minute teeth; gill-rakers reduced to slight denticles. XXVIII. *Cynodontinæ*, American.

yy. Belly rounded or the body not long and narrow.

z. No teeth on the palate; snout comparatively short; teeth all moderate in size, sometimes strong canines; gill-rakers strong; nares approximate; gill-membranes free from isthmus. XXIX. *Characinæ*, American.

zz. Teeth on the palatines.

A. Snout very elongate; palatine teeth minute, granular; anal short; intestine short. XXX. *Hydrocyninæ*, American.

AA. Snout moderate; some of the teeth canines; palatine teeth conical, in a single series; anal long; intestine short. XXXI. *Acestrorhamphinæ*, American.

x. No fontanel.

B. An adipose fin. Premaxillary with a backward projecting process between the maxillary and the palatines, the process provided with small teeth; no occipital crest; skull as in Erythrininæ. Snout much prolonged. XXXII. *Sarcodacinæ*, African.

BB. No adipose dorsal; skull above more or less truncate behind, the supraoccipital confined to the posterior surface and carinated by a rudimentary or obsolete vertical crest; adipose fin none; gill-opening wide, the membranes slightly united, free from the isthmus. Dorsal in advance of the anal, usually over or a little behind the ventrals; A. 10–13.

c. Gape very wide, premaxillary and dentaries with strong canines; lateral line developed; caudal rounded. XXXIII. *Erythrininæ*.

cc. Gape oblique; maxillary with a few slender teeth, no canines; lateral line obsolete or developed anteriorly only; caudal forked or emarginate. Walls of the air bladder normal; teeth all conical. XXXIV. *Pyrrhulininæ*, American.

Genera of Tetragonopterinæ.

a. Jaws equal, the lower not included; mandibulary teeth meeting the second of the premaxillary series. Premaxillary with two series of teeth.

b. Mandibles without conical teeth in front.

c. Gill-rakers short, lanceolate; anal long (29); lateral line complete; maxillary with conical teeth along half of its length; premaxillary and mandibular teeth as in *Tetragonopterus*. *Scissor* Günther.

cc. Gill-rakers setiform.

d. Maxillary short, the snout and maxillary together less than half length of head. Teeth of the lower jaw all alike in character and regularly graduated from in front to the last tooth on the sides; two teeth in the front row of the premaxillary on each side; teeth of the second row multicuspid incisors with contracted base, their anterior and posterior surfaces alike, convex, without distinct ridges. Lateral line complete. *Deuterodon* Eigenmann.

dd. Snout and maxillary forming at least half the length of the head; lateral line incomplete.

e. Maxillary with 0–4 teeth; jaws equal; premaxillary teeth five-pointed, in an outer row of about 8 teeth and an inner row of about 10 teeth; maxillary usually with 2 teeth; anterior mandibular teeth stronger than those of the premaxillary, 10–12 in number; sides of the lower jaw with a long row of very small single-pointed teeth.

Creatochanes Günther.

ee. Maxillary with teeth along its entire edge; lateral line very short. Species with dark lines along the sides.

f. Anterior teeth of lower jaw all alike, tricuspid; anterior pair of premaxillary teeth little larger than the rest. *Hollandichthys* Eigenmann.

ff. Lateral teeth of lower jaw enlarged, canine-like, the fourth usually largest; middle teeth of premaxillary much enlarged.

Pseudochalceus Kner.

bb. Mandibles with a pair of conical teeth behind the front series. Teeth otherwise all alike imbricate, compressed, five-pointed; dorsal placed behind ventrals; scales large. Toothed portion of maxillary-premaxillary border horizontal. *Henochilus* Garman.

aa. Lower jaw included. Teeth of the front of the lower jaw strong, graduated, with ridges on the anterior surface, those of the sides abruptly smaller (except in *Hemibrycon*) and inconspicuous; upper jaw short, the lower jaw oblique when closed, its teeth pointing backward and upward when the jaw is closed, frequently enclosed in the inner series of the upper jaw.

g. Premaxillary teeth in two series. (See also *Bryconops*.)

h. Lower jaw without a pair of conical teeth.

i. Maxillary with teeth along its entire length or nearly its entire length.

j. Lateral line interrupted. *Holopristis* Eigenmann.

jj. Lateral line complete. *Hemibrycon* Günther.

ii. Maxillary with 0–5 teeth at its anterior upper end.

k. Depth more than half the length; no predorsal spine; preventral region flat. *Tetragonopterus* Cuvier.

kk. Depth less than half the length.

l. Anal and caudal naked.

m. Lateral line interrupted. *Hemigrammus* Gill.

mm. Lateral line complete.

n. American. Maxillary frequently with teeth. More than 3 scales between ventral and l.l. *Astyanax* Baird & Girard.

nn. African. Maxillary without teeth. *Petersius* Hilgendorf.

ll. Anal or caudal scaled.

o. Anal naked; caudal scaled.

p. First and second series of premaxillary teeth in approximately parallel series. *Mœnkhausia* Eigenmann.

pp. First series of premaxillary teeth in a wavy line or imperfectly in two series. *Bryconamericus* Eigenmann.

oo. Anal and caudal scaled; anal long, convex. Postventral region compressed, the scales not passing over it.

Markiana Eigenmann.

hh. Mandible with a pair of conical teeth behind the middle of the front series.

q. Both series of teeth of upper jaw simply compressed; dorsal beginning above or behind ventrals.

r. Lateral line complete. *Micralestes* Boulenger (African).

rr. Lateral line incomplete. *Phenacogrammus* Eigenmann (African).

qq. Inner series of teeth of the upper jaw tuberculate; no maxillary teeth; a series of large, compressed multicuspid teeth in the lower jaw, similar to those in *Astyanax.*

s. A parietal, no frontal fontanel. *Brycinus* Cuv. & Val. (African).

ss. A parietal and a frontal fontanel.

t. Origin of dorsal over or behind ventrals. *Myletes* Cuvier (African).

tt. Origin of dorsal in front of ventrals; premaxillary teeth imperfectly in three series. *Bryconæthiops* Günther (African).

gg. Premaxillary teeth in three or more series.

u. Lower lip very broad, pendant. *Othonophanes* Eigenmann.

uu. Lower lip normal.

v. Mandible frequently with a pair of conical teeth behind the middle of the front series except sometimes in *Megalobrycon.*

w. Scales moderate, 35 in the lateral line; anal with 20–23 rays. *Bryconæthiops* Günther (African).

ww. Scales moderate or small, more than 45 in the lateral line; anal rays more than 20.

x. Lower jaw with a second series of teeth, at least on the sides. *Brycon* Müller & Troschel.

y. Anal rays more than 30. (*Chalcinopsis* Kner).

yy. Anal rays fewer than 30; belly not keeled.

z. Lower jaw sometimes without conical teeth (*Megalobrycon* Günther.)

zz. Lower jaw with a pair of conical teeth. (*Brycon.*)

vv. Lower jaw without a pair of conical teeth in front, and without an inner series of conical teeth on the sides.

A. Ventrals below anterior dorsal rays; anal with 32–38 rays; maxillary without teeth; premaxillary with two or three, mandible with a single series of teeth. *Bryconops* Kner.

AA. Ventrals in front of dorsal or just under anterior rays. Anal short, of 12–22 rays; maxillary with a few blunt teeth; three series of notched teeth in the premaxillary, a single series in the lower jaw. *Creagrutus* Günther.

7. CHEIRODON Girard.

Cheirodon Girard, Proc. Acad. Nat. Sci. Phila., VII, 1854, 199 (*pisciculus*).

Type: Cheirodon pisciculus Girard.

Premaxillary, mandible and sometimes the anterior part of the maxillary each with a single series of multicuspid incisors; dorsal short; opercle

not prolonged; belly rounded; gill membranes free from each other and from the isthmus.

This genus is found in the Rio Magdalena, Rio San Francisco, in the Amazon and south to the La Plata basin and from Santiago to Puerto Montt on the Pacific slope. The relationship of *pisciculus*, which enters the Patagonian area, to the other species of the genus can be expressed by the following key to the species.

a. Maxillary with a single tooth or none.

b. A black caudal spot; a bright longitudinal band on the sides; maxillary without teeth in the majority of individuals; A. 20–27, usually 21–25; scales 5 or 6–30 to 36–5 or 6, infrequently 7 scales above the lateral line; depth $2\frac{2}{5}$ to $2\frac{4}{5}$; head $3\frac{3}{5}$ to $4\frac{1}{5}$; eye $3\frac{2}{5}$ to 4. *interruptus* Jenyns.

bb. No caudal spot, or the spot very obscure; maxillary with a single tooth or none.

c. Anal 19–22; depth 2.6; head 3.6; eye 3 in head; scales 3–32–4; D. 10; an indistinct dark caudal spot; a bright silvery longitudinal band. *monodon*[1] Cope.

cc. Anal 12–15; depth 3–4; head 3–4; eye 3 in head; scales 6–33 to 36–5; D. 10–12; a silvery lateral band, no black markings. *annæ* McAtee.

aa. Maxillary with more than one tooth.

d. Anal short, of but 14 rays; D. 10; teeth usually five-pointed; a silvery lateral band margined above with black; depth 3–4 in the total length; head 5; eye 3 in head. 14. *pisciculus* Girard.

dd. Anal with 19–26 rays.

e. A black spot at base of caudal; scales 30–32.

f. Anal 23–26; no humeral spot, an intense dark violet spot on the base of caudal and continued to the tip of middle rays; a light yellow spot just behind the dark caudal spot on the upper and lower caudal rays; a conspicuous violet stripe from behind the ventrals along the entire base of the anal, a branch extending from the base of the first three or four anal rays obliquely to the tip of the 6th and 7th rays and back along the remaining rays; head $3\frac{1}{3}$–$3\frac{1}{2}$; depth $3\frac{1}{2}$–$3\frac{2}{3}$; D. 9–10; lat. line 30; mouth very oblique, lower jaw projecting; teeth numerous, very small and slender; interorbital bones entirely covering the lower cheeks. *nattereri* Steindachner.

ff. Anal 21–24; no humeral spot, sometimes a rounded spot on each side of the belly between the ventrals and anal; caudal spot continued on the middle rays but not reaching the end; sometimes a black line extending forward; head $3\frac{1}{2}$–$3\frac{2}{3}$; depth $2\frac{2}{3}$–3; eye nearly twice as long as the snout, 2.5–2.66 in the head; maxillary without teeth; D. 9; scales 32–34. *calliurus* Boulenger.

[1] The dorsal profile of one of Cope's types, kindly sent for examination by the Philadelphia Academy, is more strongly arched than the ventral and the caudal spot appears under the lens as a scattered series of contracted pigment cells. In specimens at hand of *interruptus* the ventral profile is more strongly arched than the dorsal, and the caudal spot is large and conspicuous; otherwise the species are very similar.

fff. Anal 19; humeral spot when present not conspicuous; caudal spot not continued to the tips of the middle rays; in some specimens the lower accessory rays of the caudal spine-like; D. 11; lat. line 30–31; head $3\frac{2}{5}$–$3\frac{1}{2}$; depth $2\frac{4}{5}$–3; eye little more than 2 in the head. *insignis* Steindachner.

ee. No black caudal spot; scales about 35 in a longitudinal series, 9–10 in the lateral line; intermaxillary teeth 5, mandibular 7, maxillary 2–3; depth 3 in the length; D. 11; A. (2–20) 23; eye 3 in the head. *piaba* Lütken.

14. CHEIRODON PISCICULUS Girard.

Cheirodon pisciculus Girard, Proc. Acad. Nat. Sci. Phila. VII, 1854, 199; Girard, U. S. Naval and Astronomical Expedition, 249, pl. xxxiv, figs. 4–7, 1855 (Lagoons near Santiago, Chili); Eigenmann & Eigenmann, Proc. U. S. Nat. Mus., 1891.

Chirodon pisciculus Günther, Cat. Fish. Brit. Mus. V, 332, 1864 (copied); Steindachner, Zool. Jahrb. Suppl. IV, 328, 1898 (source of Rio Maulin, Lake Llanguihue at Puerto Montt).

This species is known only from the types and from a specimen from Puerto Montt.

8. ASTYANAX Baird & Girard.

Astyanax Baird & Girard, Proc. Phila. Acad. Sci. VII, 1854; Girard, U. S. Mex. Bound. Survey, 74, 1859 (*argentatus*).

Pœcilurichthys Gill, Ann. N. Y. Lyc. Nat. Hist., 54, 1858 (*brevoortii*).

Type: Astyanax argentatus Baird & Girard.

Premaxillaries with two series of teeth, the first series with several teeth on each side; mandible with strong teeth in front and very small ones on the sides, without conical teeth in front; teeth of premaxillary equal or graduated, their crowns ridged and denticulate. Gill-rakers setiform. No predorsal spine. Maxillary with 0–10 teeth. Lateral line complete. Form slender; depth mostly more than 2 in the length.

This is one of the largest genera of Characins. Its representatives are found from the borders of the United States to the Rio Negro on the east and Peru on the west, and from Para to the Cordilleras. Some of its species have a restricted range, while others (*A. rutilus*) have a range nearly coextensive with that of the genus. *Astyanax* (forms like *rutilus*, *abramis* and *bimaculatus*) is probably one of the oldest inhabitants of South America. Its allomorphism and wide distribution would indicate its long establishment. Very near relatives of this genus are found in Africa.

The only species known to enter the Patagonian region is *Astyanax rutilus* (Jenyns).

Günther recorded this species under the name of *Tetragonopterus petenensis* from the Rio Negro. The only recorded locality of *petenensis* is Lake Peten in Yucatan. Mr. C. Tate Regan has reëxamined the Rio Negro specimens and writes me: "I have no hesitation in referring the Rio Negro specimens to *Tetragonopterus rutilus*."

Rutilus is found from Panama (possibly Mexico) to Patagonia.

The relation of this species to the other members of the genus is shown by the following key:

a. Anal rays 30 to 49.

b. Lateral line 55. Anal 45; head 3.6; depth 2.63; lat. line 55. Eye greater than snout by one-third of its diameter, greater than interorbital by $\frac{1}{5}$–$\frac{1}{6}$ of its diameter.
1. *erythropterus* (Holmberg).

bb. Lateral line with 50 scales or fewer.

c. Anal 40–48.

d. Scales 42–50.

e. Anal 47–48.

f. A few rudimentary teeth on the maxillary; a silvery lateral band; ventral profile much arched; snout pointed; A. 48. Lat. line 47.
2. *spilurus* Cuv. & Val.

ff. No teeth on the maxillary; a very distinct silvery lateral band; an indistinct caudal and humeral spot; maxillary reaching anterior margin of orbit; depth 2.3; eye 3 in the head; scales 9 or 10–47–10 or 11; A. 47. 3. *hauxwellianus* (Cope).

ee. Anal 41–45.

g. Scales 10–45 to 50–8 or 9; a small silvery lateral band; a dark spot on shoulder and another[1] on base of caudal; depth $2\frac{1}{8}$–$2\frac{2}{3}$; A. 41–45; maxillary with a single, rather large caducous tooth; eye 2.4 in the head, about equal to interorbital. Head 4.1–4.5.
4. *pelegrini* Eigenmann.

gg. Scales 8–42–7 or 8; A. 42; eye 3.7 in the head, 1.7 in the interorbital; head 3.7 in the length; a caudal spot.
5. *correntinus* (Holmberg).

dd. Scales 37 or 38.

h. Several small teeth on the maxillary; head $3\frac{3}{5}$; depth 3 or somewhat more than 3; snout 4 in the head; a silvery lateral band bordered above by blue-green; a round humeral spot; caudal spot, when present, extends to the end of some of the caudal rays. A. 43; scales 6–37 or 38–4.
6. *bairdii* (Steindachner).

hh. Maxillary with a single, small tooth. Scales in lateral line 37 or 38; both a caudal and a humeral spot very distinct, round; middle of caudal fin thickly dotted with black; maxillary not reaching orbit; head nearly 4; depth about $2\frac{3}{4}$; A. 40–42. 7. *tabatingæ* (Steindachner).

[1] These spots are very obscure in alcoholic specimens, while in specimens first preserved in formalin they are conspicuous and a black band replaces the silvery band of the alcoholic specimens.

cc. Anal 30–41.

i. Lateral line 40–50.

j. A silvery lateral band ending in a black caudal spot, sometimes two lateral spots in front; maxillary very short, without teeth, 2 in the eye; depth $2\frac{1}{2}$–3; head 4–$4\frac{1}{3}$; eye $2\frac{1}{2}$–$2\frac{2}{3}$ in head; D. 11, behind ventrals; A. 35–40. Lat. line 44–47. 8. *festæ* (Boulenger).

jj. A black band extends from base of caudal fin along its middle rays; maxillary extending to eye, its length at least $\frac{2}{3}$ the length of the eye, without teeth; eye $2\frac{2}{5}$–3 in head; depth $2\frac{2}{3}$–$2\frac{3}{4}$; head 4; A. 34–40; scales 8 or 9–40 to 50–8 or 9; last dorsal over first anal ray. 9. *brevirostris* (Günther).

jjj. Maxillary with two small teeth, equal to eye in length; eye 2.6–2.8 in head; depth 2.7–3; head 3.5–3.6; scales 8–39 to 45–6 or 7; A. 28 or 29; a dark caudal spot, not extending to end of middle rays. 38. *emperador*, which see.

jjjj. Caudal and humeral spots generally absent; origin of dorsal over ventral; interorbital wider than eye; depth 3; head 4; scales 9–40 to 46–10; A. 26–31. 37. *cordovæ*, which see.

ii. Lateral line less than 40, except sometimes in *abramis* and *bimaculatus*.

k. Anal rays 36 or fewer, rarely as many as 39 in *bimaculatus*, maxillary with a few teeth or none.

l. Depth more than three in the length, the form long and slender; maxillary without teeth.

m. Humeral and caudal spots present, anal and ventral with broad red margins; eye $3\frac{2}{3}$ in the head, much smaller than the convex interorbital. Maxillary extending to anterior margin of eye. A. 27–31; scales 7–36–7. 27. *humilis*, which see.

mm. No caudal or humeral spots; a silvery lateral band, most distinct posteriorly; head $3\frac{1}{2}$; eye $2\frac{1}{2}$ in the head. A. 30; scales 5–35–3. Maxillary toothless. 10. *astictus* (Ulrey).

ll. Depth 3 in the length. Middle rays of caudal covered by a broad band which extends to the margin of the fin and bordered above and below by yellow; a silvery lateral band; a humeral spot; head not 4 in the length. A. 27–35. Scales 7–38–7. Maxillary with a single tooth. 23. *tæniurus*, which see.

lll. Depth less than 3 in the length; a distinct caudal spot.

n. No humeral spot; depth $2\frac{1}{2}$–$2\frac{3}{5}$; eye $3\frac{2}{3}$–4 in the head; maxillary with 0–3 teeth, extending considerably beyond anterior margin of eye; a conspicuous black band on the caudal peduncle, becoming wedge-shaped on the caudal. A. 29–31. Scales 7 or 8–37 or 38–6. 11. *maximus* (Steindachner).

nn. A distinct humeral spot.

o. Maxillary long; head 3.75; depth 2.75; eye 3 in the head, $1\frac{1}{3}$ in snout, equal to interorbital; maxillary without teeth; a black humeral spot, a silvery lateral band, becoming black on the tail and extending on the caudal; origin of

dorsal over ventrals. A. 30; scales 8–37 or 38–7.

12. *moorii* (Boulenger).

oo. Maxillary extending little if any beyond origin of eye.

p. Dorsal plain.

q. Humeral spot horizontally elongate.

r. Scales in 19 or 20 rows, 10–43 to 47–8 or 9; anal 28–32. Caudal plain or with an indistinct spot; humeral spot indistinct or wanting. Dorsal distinctly behind the ventral; the pectoral reaches the ventral. Depth $2\frac{1}{2}$; head less than 4.

13. *abramis* (Jenyns).

rr. Scales in fewer than 17 rows.

s. Moderately compressed.

t. Teeth of the inner series of the premaxillary with their posterior surface convex, the denticles corresponding to the convexity arranged in a U-shaped line. Scales 6 to 8–30 to 40–5 to 8; maxillary with 0–4 teeth, extending somewhat beyond the front margin of the eye. Depth 2–2.1; head 4–4.2; eye 3 in the head. A. 27–39.

14. *bimaculatus*[1] (Linnæus).

tt. Teeth of the inner series of the premaxillary alike in front and behind, the denticles arranged in a nearly straight line; scales 6–40–6; maxillary with a single tooth, extending to below origin of pupil; depth 2.4; head 4; eye a little more than 3 in head. A. 33.

15. *orthodus* (Eigenmann).

ss. Greatly compressed. Scales 7 or 8–36 to 37–6 or 7; a humeral and caudal spot; the pectorals extend beyond

[1] The statement of Steindachner that the maxillary has minute teeth along its entire edge is evidently due to a slip of the pen; *A. brevoortii* from Trinidad has the following characters:

Scales 7–37 to 40–7; very distinct humeral and caudal spots, the latter often extending to the ends of the caudal rays; an obscure silvery band. Eye $3\frac{1}{3}$; maxillary sometimes with a single tooth. A. 29–34; var. *lineatus* from the La Plata system has more or less distinct series of spots or lines following the rows.

origin of ventrals; maxillary toothless, extending somewhat beyond front margin of orbit; head 3½–3.5; depth 2⅓–2½; A. 38–41. Very greatly compressed.
16. *caucanus* (Steindachner).

qq. Humeral spot circular or vertically elongate.

u. Depth 2–2.2; scales 8 or 9–36 to 40–8 or 9; a humeral and a caudal spot; maxillary with one tooth; head 3.66; depth 2–2.2; A. 38–39; dorsal and ventral outlines equally curved.
17. *atratoensis* (Eigenmann).

uu. Body more elongate, humeral spot very conspicuous. Anal rays 38–41. A silvery lateral band, a humeral spot. Dorsal a little behind the origin of the ventrals; the anterior anal rays elongate. Maxillary extending to near the anterior margin of the eye. Depth 2.4–2.8; head 3.5; scales 8–37 to 40-10.
18. *stilbe* (Cope).

pp. Dorsal with a broad, oblique, dark band across the middle, or plain. Scales 8–39–7; maxillary extends a little beyond the origin of the eye; D. 11; A. 31; depth 2¾; head 3⅔. 19. *bartlettii* (Günther).

aa. Anal rays 26–29, rarely 31.

v. A series of seven deep brown longitudinal bands. Maxillary extending little, if any, beyond anterior margin of eye, with one tooth. Head 3.5; depth a little more than 2 in the length. A. 27; scales 5–31–4. (See also under *bimaculatus*.)
20. *steindachneri* (Eigenmann).

vv. A single lateral band or none.

w. Caudal without vertical band.

x. Scales 28–35.

y. A caudal spot.

z. Shoulder spot horizontally oval, well defined.

A. Scales in 18 or 19 rows; A. 28–32.1 13. *abramis*, which see.

AA. Scales in 11–16 rows. 14. *bimaculatus*, which see.

AAA. Scales 7–34–6. Lateral band black. Scales in 14 rows. Dorsal fin behind the base of the ventrals. Maxillary with

1 tooth, extending a little beyond the anterior border of the eye to end of first suborbital; interorbital space much greater than the eye, very convex; eye 4 in head. Head 3⅔; depth 3; A. 28. A humeral spot.

21. *wappi* (Cuv. & Val.).

AAAA. Scales 7–36–7; maxillary extending to eye; eye 3.66 in head, much smaller than the convex interorbital; A. 27–31; anal and ventral with broad red margins.

30. *humilis*, which see.

zz. Shoulder spot, if present, vertically elongate, sometimes faint.

B. Caudal spot band-like, continued on the middle caudal rays; scales in fewer than 15 rows.

C. A humeral spot.

D. Dorsal behind the ventrals.

E. Maxillary with 2–7 teeth; anal 27–32; depth 2½–3[1]; head about 4; maxillary equal to eye; eye 3 in head, equal to intraorbital. Scales 7–37–6

22. *rutilus nicaraguensis* Eigenmann.

EE. Maxillary with 0–2 teeth.

F. Maxillary extending distinctly beyond the anterior margin of the eye. Head 4–4½; depth 2.25–3; A. 24–32; scales 6 or 7–30 to 39–4½ to 6. 23. *rutilus*[1] (Jenyns).

FF. Caudal band bordered by yellow above and below; head not 4 in the length; maxillary with a single tooth; A. 27–35; scales 7–38–7.

24. *tæniurus* (Gill).

FFF. A. 24–32; origin of the dorsal behind the base of the ventrals; maxillary with from 0–2 teeth, reaching anterior border of the orbit; head 4; depth 2.25–2.75; scales 7 to 9–35 to 39–6 or 7. 25. *rutilus æneus* (Günther).

FFFF. Depth 3.33; head 3.66; A. 29; scales 7–37–5; maxillary long, equal to eye; eye 2.5 in the head; interorbitals 3.66. 26. *cuvieri* (Lütken).

DD. Dorsal over ventrals; snout less than 4 in head; interorbital flattish; A. 27, beginning behind the dorsal; depth 3; head 4; lat. l. 37.

27. *petenensis* (Günther).

[1] *Rutilus jequitinhonhæ* has depth 3.

CC. No humeral spot (Western Peru and Ecuador).

G. Dorsal behind ventrals; snout about 4 in the head; interorbital convex. A. 26–30, beginning under last ray of dorsal; depth 3–3½; head 3⅜–4. Scales 6 or 7–36 to 40–7; 2 or 3 maxillary teeth. A silvery lateral band which may become black on the caudal. 28. *simus* (Boulenger).

GG. Head 3½–4⅓; depth 2¾–3; interorbital much more than diameter of the eye. Maxillary terminates below the anterior margin of the eye, with 2 teeth; origin of dorsal behind the ventrals. A. 26–30; scales 6–35 to 37–6 to 8. 29. *peruanus* (Müller & Troschel).

BB. Caudal spot not continued on the middle rays.[1]

H. Scales in 15 rows, 7–36–7; A. 27–31; depth more than 3 in the length; eye 3.66 in the head, much smaller than the convex interorbital; a humeral spot and a caudal spot. 30. *humilis* (Günther).

HH. Scales in 10–14 rows; lateral line 34–38.

I. Head 4 or less than 4 in the length.

J. A humeral spot; maxillary reaching anterior border of eye, not to end of first suborbital; head 3.75–4; depth 2.4–2.7; A. 23–28; scales 6½ or 7½–34 to 37–5½ to 6½. Two or three maxillary teeth. 31. *fischeri* (Steindachner).

JJ. Maxillary ceases in front of the vertical from the pupil, and end of first suborbital. Dorsal considerably behind origin of ventrals; pectorals reaching beyond ventrals. Eye about equal to the slightly convex interorbital, 3 in the length of the head. Depth 2¾; head 3⅜; A. 26; scales 6½–37 or 38–5; a humeral spot. 32. *carolinæ* (Gill).

II. Head 4 or less in the length. Scales 5½–35–4. Anal, dorsal and caudal fins with red markings. Caudal and humeral spots indistinct. Head 4.2; depth 3.75; A. 25–29. 33. *phœnicopterus* (Cope).

yy. No caudal spot;[2] a humeral spot.

K. Maxillary with three small teeth; eye 2.3 in head, snout 4.5, the flattish interorbital 3; depth 2.66; head 3.6; A. 28; scales 5–35–4; a silvery lateral band, a vertical humeral spot. 34. *megalops* (Eigenmann & Ogle).

[1] Not examined in *carolinæ* and *humilis*.

[2] Not stated for *bahiensis*.

KK. Maxillary with numerous minute teeth, extending beyond the front of the orbit. Snout shorter than eye. Eye 2.8–3. A. 29–30; scales 5 or 6–32 or 33–4 to 5. Head 3.6; depth $2\frac{1}{4}$–$2\frac{1}{2}$; humeral spot elongate horizontally.

35. *bahiensis* (Steindachner).

KKK. Maxillary without teeth. Silvery band not edged with green above; origin of dorsal between ventral and anal; pectorals to origin of ventrals, ventrals nearly to anal. Head $4\frac{2}{3}$; depth $3\frac{1}{2}$; eye $2\frac{3}{11}$ in head; D. 10; A. 27; scales 5–37–3.

36. *alburnus* (Hensel).

xx. Scales 9–40 to 46–6–8; longitudinal series of scales 14–17. Caudal and humeral spots generally absent; origin of dorsal over root of ventrals. Width of interorbital greater than the diameter of the eye. Head 4; A. 26-30. Interorbital very convex, $2\frac{2}{3}$ in head; eye equals snout, $3\frac{2}{3}$ in head; depth of caudal peduncle about $\frac{1}{3}$ of the depth. 37. *cordovæ* (Günther)

xxx. Scales in 15 or 16 rows, 8–39 to 45–7; A. 28 or 29; head 3.6 or 3.5; depth 2.7–3; eye large, 2.6–2.8; interorbital 3.25 in head; maxillary as long as eye, with two narrow teeth; dorsal behind origin of ventrals; humeral spot faint; caudal spot distinct, not continued on middle rays.

38. *emperador* (Eigenmann & Ogle).

aaa. Anal rays 16–25, rarely 26 and 27 in *fasciatus* and *æneus*; 3 to 5 series of scales below the lateral line in all but *æneus* (6 or 7) and *fasciatus* ($4\frac{1}{2}$–7). Caudal without black cross band.

L. Maxillary without teeth; two or three scales below the lateral line.

M. No caudal spot.

N. Depth 4.7 in the length; longitudinal series of scales 12. A broad silvery lateral stripe; no caudal spot. Maxillary toothless, rather wide, extends little beyond anterior border of the orbit. Head 4.2; depth 4.7; A. 25. 39. *longior* (Cope).

NN. Depth 2.5–3.5 in the length.

O. A silvery lateral band sharply edged above with a dark band. Dorsal fin a little behind the ventrals. The pectorals not entirely reaching the ventrals, the ventrals reaching the anal. Head 3.8; depth 3–$3\frac{2}{4}$; scales 5–32–3. A. 21–22. 40. *copei* (Steindachner).

OO. The broad silvery lateral band not edged above with dark. Maxillary extending nearly to the front margin of the eye; anterior dorsal and anal rays elongate. Head 4.4; depth $3\frac{1}{7}$; scales 4–35–3; A. 19. 41. *diaphanus* (Cope).

OOO. The narrow silvery band edged with greenish above. Origin of the dorsal just behind the ventral; the pectoral reaches to the middle of the base of the ventral. Head 3.4–3.75; depth 2.8–2.86; A. 24–25; scales 5–32 or 33–3. 42. *collettii* (Steindachner).

LL. Maxillary with teeth.

P. Middle caudal rays black.

Q. One to three teeth in the maxillary.

R. A. 18–25. A silvery-gray lateral band, a dark caudal spot fading out forward. Usually a humeral spot. Maxillary with two small teeth. Head 4; depth $2\frac{3}{4}$–3; scales 7 or 8–37 to 40–3; eye 3 in head. 43. *mexicanus* (Filippi).

RR. A. 24–27. Origin of the dorsal behind the base of the ventrals; maxillary toothless, or with one or two teeth, reaching anterior border of the orbit. Head 4; depth $2\frac{1}{4}$–$2\frac{3}{4}$; scales 7 to 9–35 to 39–6 or 7. 25. *æneus* (Günther).

RRR. A. 18–25. A dark caudal spot extending to the end of some of the rays and fading out anteriorly; a silvery lateral band; an indistinct humeral spot; ventral and pectoral fins with red. Head 4, longer than its depth at the occiput; depth $2\frac{1}{2}$–3; scales 5 or 6–32 to 40–$4\frac{1}{2}$ to 6 rarely 7. 44. *fasciatus* (Cuvier).

RRRR. A. 25–30; depth 2.6–2.66. 23. *rutilus.*

RRRRR. A. 3.16–19. Three or four scales below the lateral line. Head 4–$4\frac{1}{3}$; depth $2\frac{1}{2}$–3; scales 5–35 to 37–3 or 4. A. 3, 16–19. 45. *fasciatus iheringii* (Boulenger).

QQ. Numerous minute teeth on the maxillary which extends either a little or distinctly behind the front margin of the orbit. Eye small 3.5–4 in the head. A vertically elongate humeral spot and a longitudinal caudal stripe extending to the end of the rays and fading out anteriorly. Head $3\frac{1}{4}$–$3\frac{3}{4}$; depth 3–$3\frac{1}{3}$; scales 5–33–4. A. 16–18. 46. *jenynsii* (Steindachner).

PP. Middle caudal rays not black.

S. Scales in lateral line 34–38.

T. A. 23–28; depth 2.4–2.7; scales $6\frac{1}{2}$ or $7\frac{1}{2}$–34–37–$5\frac{1}{2}$–$6\frac{1}{2}$. 31. *fischeri*, which see.

TT. A. 19 or 20.[1] Almost colorless; caudal rays sometimes dusky, a grayish lateral band. Pectorals reaching $\frac{2}{3}$ to ventrals, ventrals $\frac{2}{3}$ to anal. Maxillary, with two teeth, reaching to eye. Head 4; depth 3.2–3.75; scales 4 or 5–35 to 38–4. 47. *mœnkhausi* (Eigenm. & Kennedy).

TTT. Anal 17–18. Yellowish above, white on the sides; lateral band plumbeous above, silvery below, a plumbeous humeral spot. Head $4\frac{1}{4}$ to $4\frac{1}{3}$; eye $2\frac{1}{2}$ in head; depth 3.2–1.6. Lateral line 34–36. Dorsal band, large part of anal, the body near it and the median spot of the caudal more or less red. 48. *rubropictus* (Berg).

TTTT. A. 18; scales 37 or 38; depth $3\frac{1}{5}$; head $4\frac{1}{5}$; plumbeous, fins dusky; pectorals reaching ventrals; ventrals nearly to anal; caudal lobes rounded; snout blunt, lower jaw distinctly shorter than upper; a faint humeral spot. Mouth very small, maxillary not reaching eye; eye $3\frac{1}{2}$ in head, interorbital very convex, less than 3 in head; depth of caudal peduncle little less than half the greatest depth. 49. *eigenmanni* Evermann & Kendall.

[1] 26 in one specimen.

SS. Scales 5–31–3. Silvery lateral band; a diffuse caudal spot; no humeral spot. Head $3\frac{1}{2}$; depth $2\frac{3}{4}$. A. 19. 50. *paucidens* (Ulrey).

15. Astyanax rutilus (Jenyns).

(Plate XXXIV, Fig. 4.)

Tetragonopterus rutilus Jenyns, Zool. Beagle, Fishes, 125, pl. 23, fig. 2, 1842; Steind., Ichthyol. Notizen, IX, 10, pl. ii, figs. 2 and 3, 1869 (Montevideo); Hensel, Wiegm. Archiv, 1870, 80; Steind. Tetragonopterus microstoma Günther, Cat. Fish. Brit. Mus. V, 323, 1864; Günther, Ann. & Mag. Nat. Hist. July, 1880 (Rio Plata).

Tetragonopterus æneus, Hensel (not Günther); Wiegm. Archiv. 1870, 87 (Southern Brazil).

Tetragonopterus jequitinhonhæ Steind., Süsswf. Südöstl. Bras., III, 27, pl. ii, fig. 3, 1876 (Jequitinhonha); E. & E., Proc. U. S. Nat. Mus., XIV, 1891, 52; Ulrey, Ann. N. Y. Acad. Sci. VIII, 280, 1895; Eigenmann & Norris, Revista Museo Paulista, 357, 1900 (Piracicaba).

Habitat: Rio Negro, Patagonia to Mexico, in all streams of the eastern slope of South America; Western Ecuador.

Of this species Steindachner says: "Almost every river system possesses a peculiar variety of this species; according to age, sex, season; according to abundance or scarcity of food; according to the habitat in cool or clear mountain brooks or deeper stagnant waters, the outlines of the body vary, and in part also, the number of horizontal rows of scales and of the anal rays."

A single specimen has been recorded from the Rio Negro. It is preserved in the British Museum and is reproduced in fig. 4, plate XXXIV.

Order IV. HAPLOMI.

Cope, Proc. A. A. A. Sci., Indianapolis, 1872, 328 and 333; Gill, East Coast Fishes, 1872, 14.

"Air-bladder, if present, communicating with the digestive tract by a duct. Opercle well developed. Pectoral arch suspended from the skull; no mesocoracoid arch. Fins usually without, rarely with a few spines; ventrals abdominal, if present. Anterior vertebræ distinct, without Weberian ossicles." Boulenger.

The boundaries of this order are differently conceived by different authors and most of the constituent families are extralimital. It includes three families with representatives in South America. Of these, one, the Pœciliidæ, which is dominant in Central America and whose species straggle north through the temperate zone and south to Buenos Aires, is

not known to have representatives in Patagonia. The three families may be distinguished as follows:

a. Parietals separating the frontal from the supraoccipital; post-temporal simple; precaudal vertebræ with autogenous parapophyses.

b. Margin of the upper jaw formed by the premaxillaries and the maxillaries; basis cranii simple; no adipose dorsal fin. *Galaxiidæ.*

bb. Margin of the upper jaw formed by the premaxillaries only; basis cranii double; adipose dorsal fin present. *Aplochitonidæ.*

aa. Frontals in contact with the supraoccipital; precaudal vertebræ without well developed parapophyses; border of mouth formed by premaxillaries only; dorsal and anal without spines; scales cycloid, or with erect spines; no adipose fin; mouth protractile; ventral fins if present with 5–7 rays. *Pœciliidæ.*

Family V. *GALAXIIDÆ.*

Galaxiæ Müller, Abhandl. Akad. Wiss. Berlin, 1844, 187.
Galaxidæ Günther, Cat. Fish. Brit. Mus. VI, 208, 1866.

This family consists of two genera,[1] *Neochanna* with a single species inhabiting New Zealand, where it sometimes burrows in damp clay some distance from water, *Galaxias* with 26 recognized species, of which six are found in southern South America or adjacent islands, two at the Cape of Good Hope, and the remainder in New Zealand, Tasmania and Australia. One of them, *attenuatus*, is probably common to American, Australian and New Zealand waters. The species range from the ocean to an elevation of 6,000 feet. Some are evidently land-locked, while others descend to the sea to spawn.

The *Galaxias* of the Cape of Good Hope is the only type of fishes south of the tropic of Capricorn in Africa that is not found north of it.

Neochanna is distinguished from *Galaxias* by the absence of ventrals.

9. GALAXIAS Cuvier.

Galaxias Cuvier, Règne Animal, II, 183, 1817 (*truttaceus*).
Mesites Jenyns, Voy. Beagle, Fishes, 118, 1842, sp.
Austrocobitis Ogilvie, Proc. Linn. Soc., New South Wales, XXIV, 1899, 158, (*fide* Regan).

Boulenger (Nature, Nov. 27, 1902) says concerning *Galaxias:* "Most text-books and papers discussing geographical distribution have made much of the range of a genus of small fishes, somewhat resembling trout,

[1] *Cromeria* from the White Nile has been shown to be not related to the *Galaxiidæ.*

the *Galaxias*, commonly described as true fresh-water forms, which have long been known from the extreme south of South America, New Zealand, Tasmania and southern Australia. The discovery, within the last few years, of a species of the same genus in fresh water near Cape Town, whence it had previously been described as a loach by F. de Castelnau, has added to the interest, and has been adduced as a further argument in support of the former existence of an Antarctic continent. In alluding to this discovery, when discussing the distribution of African fresh-water fishes in the introduction to my work 'Les Poissons du Bassin du Congo,' in 1901, I observed that, contrary to the prevailing notion, all species of *Galaxias* are not confined to fresh-water, and that the fact of some living both in the sea and in rivers suffices to explain the curious distribution of the genus; pointing out that in all probability these fishes were formerly more widely distributed in the seas south of the tropic of Capricorn, and that certain species, adapting themselves entirely to fresh-water life, have become localized at the distant points where they are now known to exist. Although as recently as October last the distinguished American ichthyologist D. S. Jordan, wrote (Science, XIV, p. 20): 'We know nothing of the power of *Galaxias* to survive submergence in salt water, if carried in a marine current,' it is an established fact, ascertained some years ago by F. E. Clarke in New Zealand and by R. Vallentin in the Falkland Islands, that *Galaxias attenuatus* lives also in the sea. In New Zealand it periodically descends to the sea, where it spawns, from January to March and returns from March to May. In accordance with these marine habits, this species has a much wider range than any of the others, being known from Chile, Patagonia, Tierra del Fuego, the Falkland Islands, New Zealand, Tasmania, and southern Australia.

"I now wish to draw attention to a communication made by Captain F. W. Hutton in the last number of the Transactions of the New Zealand Institute (XXXIV, p. 198), 'On a Marine Galaxias from the Auckland Islands.' This fish named *Galaxias bollansi*, was taken out of the mouth of a specimen of *Merganser australis* during the collection excursion to the southern islands of New Zealand made in January, 1901, by His Excellency the Earl of Ranfurly.

"It is hoped that by giving greater publicity to these discoveries the family *Galaxiidæ* will no longer be included among those strictly confined to fresh waters, and that students of the geographical distribution of animals

will be furnished with a clue to a problem that has so often been discussed on insufficient data."

The species of this genus recorded from Patagonia have received elaborate consideration from Smitt. He found that the young differs greatly from the adult and that three stages may be distinguished, "alevins," less than 45 mm., "fretins," about 50 mm., and adult, over 60 mm. Species based on these larval stages are scarcely recognizable. The difference between the alevins and the fretins of the same species is greater than the differences between two adult species. The only character distinguishing the species in all ages is the length of the lower jaw in relation to the distance of the dorsal from the tip of the snout.

He distinguishes the two species recognized by him as follows:

a. Head 18.8–20.1 per cent. of the length; distance of origin of dorsal from tip of snout 72–74.8 per cent. of the length; distance of origin of ventrals from tip of snout 48.5–52.1 per cent. of the length; pectoral 11; A. 13–15; lower jaw 9.3–10.2 per cent. of the length from tip of snout to dorsal. *maculatus.*

aa. Head 22.4–26.6 per cent. of the length; distance of origin of dorsal from tip of snout 53.8–56.6 per cent. of the length; P. 13–15; A. 9–12; lower jaw 12.9–16.3 per cent. of the distance from tip of snout to dorsal. *alpinus.*

The color of the alevins of both species is uniform yellowish or gray. In the alevins of *maculatus* a series of pigment cells follows the dorsal border posteriorly; another follows the ventral border and alimentary canal; another series along the lateral line, another along the upper margin of the notochord; a black bar at base of pectoral; a black spot at upper angle of preopercle and others on snout and top of head.

During the fretin stage the color of the two species is alike and remains so till the species has reached a length of about 8.5 cm.

More recently Regan, Proc. Zool. Soc. London, 1905, II (April 1906), considered the fretins of Smitt as a distinct species, *gracillimus* of Canestrini. Smitt's *alpinus* he considers in part *attenuatus*, in part *maculatus* and in part *platei*.

Regan defines six American species of which *alpinus* is confined to the alpine lakes of Hardy Peninsula, Tierra del Fuego, and *smittii* to the Falkland Islands. The remaining four are distinguished as follows:

a. Six or seven branchiostegals; caudal emarginate; origin of anal opposite or slightly posterior to that of the dorsal.

b. Origin of ventral equidistant from tip of snout and base of caudal or nearer the former.

c. Length of head 5 (young) to $6\frac{1}{2}$ (adult) in the length; depth $5\frac{1}{2}$–10; snout a little longer than eye (in the adult), smaller than interorbital; origin of ventral equidistant from tip of snout and base of caudal; depth of caudal peduncle $\frac{1}{3}$ to 2 in its length; upper parts of head and body finely punctate with blackish and spotted or marbled with dark purplish. Recorded specimens 55–170 mm. 16. *attenuatus.*

cc. Length of head 7–$7\frac{1}{2}$ (young) in the length; depth 10–12; snout a little shorter than eye, less than interorbital; origin of ventrals nearer tip of snout than base of caudal; caudal peduncle $2\frac{1}{2}$ times as long as deep; some small blackish spots on the head and on the upper part of the body; a line of black dots along the middle of the side and one at the base of each of the unpaired fins. Recorded specimens reaching a length of 55 mm. *gracillimus.*[1]

bb. Origin of ventral nearer to base of caudal than to tip of snout.

d. Maxillary extending to below anterior margin of eye or slightly beyond; depth 6–8; head $4\frac{1}{2}$–$5\frac{3}{4}$; snout nearly as long as eye which is $3\frac{1}{2}$–$4\frac{1}{3}$ in the head; interorbital $2\frac{3}{5}$–3; jaws equal; origin of ventral equidistant from middle of pectoral and origin of anal; caudal peduncle $1\frac{1}{2}$–2 times as long as deep; numerous irregular blackish spots. Recorded specimens 73–120 mm. 17. *maculatus.*

aa. Eight or nine branchiostegals; caudal truncate or emarginate; origin of anal behind that of dorsal; origin of ventral considerably nearer to base of caudal than to tip of snout; depth 5–6; head $4\frac{1}{4}$–$4\frac{3}{4}$; snout longer than eye, which is 5–$7\frac{1}{2}$ in head; interorbital $2\frac{1}{2}$–$2\frac{3}{5}$; jaws equal; maxillary extending beyond origin — frequently to middle of eye; caudal peduncle as long as deep or a little longer; head, body and fins covered with numerous irregular dark spots. Recorded specimens 49–300 mm. 18. *platei.*

16. GALAXIAS ATTENUATUS (Jenyns).

Only the Patagonian synonymy and bibliography are given. The species is also found in Tasmania, Australia, New Zealand.

Mesites attenuatus Jenyns, Voyage Beagle, Fishes, 121, pl. xxii, fig. 5, 1842. (Bay Islands, New Zealand.)

Galaxias attenuatus Günther (in part), Cat. Fish. Brit. Mus., VI, 210, 1866 (Falkland Islands; Peru?); Günther, Zool. Coll. H. M. S. Alert, 21, 1881 (Puerto Bueno); Vaillant, Miss. Scient. Cap Horn, Poiss. C. 19, 1888 (Orange Bay); Perugia, Ann. Mus. Civico Storia Nat. Genova, (2*a*), X, 54, 1891 (Lake and River of Porto Cook); Philippi, Verh. Deutsch. Wiss. Ver. Santiago, Chile, III, 21, 1895. Delfin, Catalogo Peces Chile, 33, 1901 (Chiloe); Dollo, Voy. Du S. Y. Belgica, pl. x, fig. 5.

Galaxias maculatus (non Jenyns) Richardson, Voy. Erebus and Terror, 75, pl. xvii, figs. 14–117, 1847 (Falkland Islands); Smitt, Bih. Svenska Akad. Handl. XXVI, IV, No. 13, 1901, p. 21, pl. ii, figs. 5–8 (Rio Pescado and Ultima Esperanza).

[1] This is undoubtedly the young of *attenuatus.*

Mesites gracillimus Canestrini, Arch. Zool. Anat. Fisiol. III, 1864, 100, tav. 4, f. 2. (Chile).

Galaxias gracillimus Günther, Cat. Fish. Brit. Mus. VI, 213, 1866; Philippi, Verh. Deutsch. Wiss. Ver. Santiago, Chile, III, 21, 1895; Delfin, Catalogo Peces Chile, 34, 1901; Regan, Proc. Zool. Soc., London, 1905, II, 370 (Falkland Islands).

? *Galaxias minutus* Philippi, Wiegemann's Archiv. XXIV, 1858, 309; Verh. Deutsch. Wiss. Ver. Santiago, Chile, III, 21, 1895 (Valdivia); Delfin, l. c., 34, 1901.

? *Galaxias punctatus* Philippi, Wiegemann's Archiv., XXIV, 1858, 310; Verh. Deutsch. Wiss. Ver. Santiago, Chile, III, 21, 1895; Delfin, l. c. (Valdivia and Puerto Montt.)

Galaxias alpinus (non Jenyns) Smitt, 21, pl. ii, figs. 9–12, (Rio Azopardo; Rio Pescao; Rio Gallegos; alpine lakes of the Sierra Toro and Lago Toro basin); Delfin, l. c., 34, 1901.

Habitat: (Peru?) Puerto Montt south to Falkland Islands and Australia, Tasmania, New Zealand. No specimens were secured by Hatcher.

17. Galaxias maculatus (Jenyns).

(Plate XXXV, Fig. 4.)

Stomias variegatus Lesson, Voy. La Coquille, II, 142, 1830 (Malouines).

Mesites maculatus Jenyns, Zool. Voyage Beagle, Fishes, 119, pl. xxii, fig. 4, 1842 (Fresh-water brook in Hardy Peninsula, Tierra del Fuego; higher tributaries of the Rio Santa Cruz).

Galaxias maculatus Cuvier & Valenciennes, Hist. Nat. Poiss. XVIII, 355, 1848 (Malouines); Günther, Cat. Fish. Brit. Mus., VI, 212, 1866; Vaillant, Miss. Scient. Cap Horn, Poiss. C. 18, 1888 (Fresh-water of Orange Bay); Perugia, Ann. Mus. Civico Storia Nat. Genova (2*a*) X, 54, 1891 (Lake and River of Porto Cook); Philippi, Verh. Deutsch. Wiss. Ver. Santiago, III, 21, 1895; Steindachner, Zool. Jahrb., 1898, Suppl. IV, 328 (Rio Pescado near Punta Arenas); Delfin, Catalogo Peces Chile, 33, 1901 (Puerto Montt; Valdivia); Dollo, Voy. Du S. Y. Belgica, 80, pl. x, fig. 4, 1904 (Lapataia, Beagle Channel); Regan, Proc. Zool. Soc. Lond., 1905, II, 370 (Alert Bay; Orange Bay; Falkland Islands, Esterode Penco): Evermann & Kendall, Proc. U. S. Nat. Mus. XXXI, 1906, 91 (Lake Nahuel Huapi, one of the sources of the Limay River; elevation 2,500 feet).

Galaxias coppingeri Günther, Proc. Zool. Soc. London, 1881, 21 (Alert Bay); id. Zool. Coll. H. M. S. Alert, 21, 1881. (Alert Bay.)

Galaxias alpinus (non Jenyns) Smitt, Bih. Svenska Akad. Handl. XXIV, IV, No. 5, 1898, p. 56, pl. v, figs. 40–40*a*.

Habitat: Falkland Islands, Tierra del Fuego, Patagonia.

18. GALAXIAS PLATEI Steindachner.

(Plate XXXV, Figs. 1, 2, 2*a*, 3 and 3*a*.)

Galaxias platei Steindachner, Zool. Jahrb., 1898, Supplement IV, Zweites Heft, 329 (Rio Pescado near Punta Arenas); Delfin, Catalogo Peces Chile, 34, 1901.

Galaxias alpinus (part) Smitt, Bih. Svenska Akad. Handl. XXVI, IV, No. 13, p. 9, pl. iii, 1901.

? *Galaxias grandis* Philippi,[1] Verh. Deutsch. Wiss. Ver. Santiago, Chile III, 19, 1893; Delfin, Catalogo Peces Chile, 33, 1901 (Punta Arenas).

? *Galaxias delfini* Philippi, Verh. Deutsch. Wiss. Ver. Santiago, Chile III, 19, 1893; Delfin, Catalogo Peces Chile, 33, 1901 (Punta Arenas).

? *Galaxias titcombi* Evermann & Kendall,[2] Proc. U. S. Nat. Mus. XXXI, 1906, 92 (Rio Traful, Argentina).

[1] Philippi described two species of *Galaxias* as follows:

Galaxias grandis Philippi, p. 19, based on a specimen shrivelled by strong alcohol and from which all fins but the caudal had been removed, from a lake north of Punta Arenas. Length without caudal 292 mm., with caudal 330 mm.; depth 3.4 in the length, width 3.56; depth of caudal peduncle 10.8, its width 32.4 in the length; head 4.5. Head low, flat above and little arched; mouth small, eye 9 + in the head; four ridges on preopercle. Dorsal profile more strongly arched than in other species of *Galaxias*, ventral profile but little arched. Head light gray, body yellowish, lighter below; numerous spots 1½ mm. in diameter everywhere on the body, fainter ones on upper part of head.

Galaxias delfini Philippi, p. 19, based on a specimen preserved in such strong alcohol that it had to be soaked in water before its characters could be made out. From a lake north of Punta Arenas. Length without caudal 192 mm.; depth 5.8 in the length; width less than depth; depth of caudal peduncle 1.2 in the length; head a little over 4.5; depth of head greater than in *grandis* but equally flat; eye 9 in head; dorsal and ventral profiles nearly straight; base of dorsal 8.7 in the length, its height 7; back light yellow, sides light gray; back with numerous partially confluent brown spots; fins unspotted. D. 8; A. 12.

[2] This species, which may be distinct, was published as this report was going through the press. It was described as follows:

Head 4 in length without caudal; depth 5.94; eye 4.23 in head; snout 3.92; D. 10; A. 11; snout bluntish; eye moderate, slightly shorter than snout; dorsal outline arching slightly from occiput, thence nearly straight to front of dorsal; height of dorsal 8.56 in length without caudal, its base about 2.20 in head, the first rays when depressed not reaching tip of last rays; distance

Habitat: Chili to Punta Arenas and Rio Chico.

Twenty-four specimens, ranging from 49–96 mm., were collected by Hatcher in the Rio Chico, 15 miles below Rio Belgrano, and eight between 48 and 113 mm. near Punta Arenas. The oldest specimen is finely mottled with irregular light cross streaks. The light becomes more marked in the specimen 90 mm. long. Of two specimens 87 mm. long one is colored like the largest, the other has dark blotches and cross streaks on a yellow background. With a decrease in the size there is an irregular decrease in the amount of pigment which is in cross streaks and irregular blotches.

Family VI. *APLOCHITONIDÆ.*

Haplochitonidæ Günther, Cat. Fish. Brit. Mus. V, 381, 1864.

The family is composed of two genera, the naked *Aplochiton* with two species in Chili and Patagonia, and the scaled *Prototroctes* with three species in New Zealand, Queensland and South Australia.

The species of *Aplochiton* have also received detailed consideration from Smitt.

10. APLOCHITON Jenyns.

Aplochiton Jenyns, Voy. Beagle, Fishes, 131, 18.
Farionella Cuvier & Valenciennes, Hist. Nat. Poiss. XXII, 507.
Haplochiton Günther, Cat. Fish. Brit. Mus. V, 381, 1864.

Species of Aplochiton.

a. D. 12–13; A. 15–16.

b. Head 22.5–25.9 per cent. of the length; width of head 11.3–12.4 per cent.; olivaceous, darker above, a series of narrow dark cross bars. 19. *zebra.*

from tip of snout to origin of dorsal about 1.46 in length without caudal; height of anal about 8.46 in same length, its base about 2.20 in head, the tips of first rays not reaching tips of last when depressed; distance from tip of snout to anal origin about 1.32 in the length without caudal; pectoral short, rounded; ventral very short, about 2.5 in head, the distance from its origin to base of pectoral about 3.35 in length without caudal, and distance from its origin to point of anal about 5.25 in same length; caudal deeply emarginate.

Color, very pale gray, slightly more dusky on back from thick minute punctulations; irregular groups of black dots on side extending not quite to belly, giving a clouded effect and the appearance of broken and entire crossbars; belly pale, with very few dots in front of ventral; a row of black dots from base of each ventral to each side of vent; fins pale, with some punctulations, head thickly punctulated above, on snout, and on side about to level of upper jaw, abruptly pale below.

Type. — A specimen 5.62 inches long, collected December 13, 1903, by Mr. John W. Titcomb, from Rio Traful near Lake Traful, Argentina.

bb. Head 20–21.1 per cent. of the length; width of head 9.2–9.5. Lighter, no bars.
20. *tæniatus.*

19. APLOCHITON ZEBRA Jenyns.

(Plate XXXV, Figs. 5 and 5*a*.)

Aplochiton zebra Jenyns, Zool. of the Voyage of the Beagle, Fishes, 131, pl. xxiv, fig. 1 (Falkland Islands).

Haplochiton zebra Günther, Cat. Fish. Brit. Mus. V, 381, 1864 (Port Louis) Günther, Zool. Coll. H. M. S. Alert 1881, 22 (East Bay, freshwaters at Tom Bay); id. Rep. Voy. Challenger, Shore Fishes, 23, 1889; Smitt, Bih. Svenska Akad. Handlinger, XXVI, Afd. IV, No. 13, 1901, 1 (Rio Tres Pasos, a tributary of Lago Toro); Delfin, Catalogo Peces Chile 32 (Puerto Montt; Rio Renaico; Puerto Otuai).

Farionella gayii, Cuvier & Valenciennes, Hist. Nat. Poiss. XXII, 508, pl. 640.

Habitat: Puerto Montt, south to the Falkland Islands.

20. APLOCHITON TÆNIATUS Jenyns.

(Plate XXXV, Figs. 6 and 6*a*.)

Aplochiton tæniatus Jenyns, Zool. of the Voy. of the Beagle, Fishes, 132, 1842, pl. xxiv, fig. 2 (Mouth of freshwater streams, Gore Sound, Tierra del Fuego).

Haplochiton tæniatus Günther, Cat. Fish. Brit. Mus. V, 382, 1864 (Gore Sound); Smitt, Bih. Svenska Akad. Handl. XXVI, Afd. IV, 1, 1901 (Lago Toro); Delfin, Catalogo Peces Chile, 32, 1901; Dollo, Voy. du S. Y. Belgica, 81, 1904 (Lapataia, Beagle Channel).

Habitat: Southern Patagonia and Tierra del Fuego.

Order V. ACANTHOPTERI.

Anterior vertebræ unmodified; no mesocoracoid and no interclavicles; mouth border formed by premaxillary; shoulder girdle attached to skull by a post temporal; anterior rays of dorsal and anal usually spinous; air bladder usually without duct.

Including the majority of marine fishes and many fresh-water species.

Suborder Percesoces.

Cope, Trans. Am. Philos. Soc. XIV, 456.

Ventral fins abdominal, with one spine and five soft rays; gills and mouth normal.

Two of the families of this suborder have representatives in South American fresh waters. They may be distinguished as follows:

a. Ribs attached to strong parapophyses; teeth small or wanting; gill rakers long and slender; pectoral fins inserted high up.

b. Pelvic bones free or connected with the clavicle by ligament; carnivorous; head elongate; vertebræ more than 35; dorsal spines slender, flexible, 1–8 in number; stomach not gizzard-like. *Atherinidæ.*

bb. Pelvic bones suspended from the postclavicles; teeth feeble or absent, limnophagous; head short and broad; vertebræ about 24; stomach gizzard-like; intestines very long. *Mugilidæ.*

The *Mugilidæ* are chiefly marine, some enter or are permanently established in fresh water, none are recorded from Patagonian fresh waters.

Family VII. *ATHERINIDÆ.*

The *Atherinidæ*, like the *Mugilidæ* are chiefly marine. A number of genera or species have become established in fresh water; thus species of *Atherina* and *Menidia* are established in fresh water in Cuba and North America. *Labidesthes* is a genus confined to the fresh waters of the eastern slope of the United States. *Lethostole* and *Chirostoma* are fresh-water fishes of Mexico. *Protistius* is found in the Peruvian Andes at an altitude of 12,000 feet; *Gastropterus* on the Pacific slope to an elevation of 7,500 feet.

Along the coast of Chili and Patagonia and entering its rivers or established in its lakes are found several species of *Atherinopsis* and *Menidia.*

The genera represented in the waters of Patagonia may be distinguished as follows:

a. Premaxillaries freely protractile, broad posteriorly, their edge strongly curved; jaws nearly equal, the lower slightly shorter, forming a pointed muzzle; scales large, smooth; first dorsal rounded; belly rounded; anal about 14–19; teeth minute, in bands; dorsal and anal naked. *Menidia.*

aa. Premaxillaries not protractile, the skin of upper jaw mesially continuous with that of the forehead; teeth simple, pointed, in villiform bands; vomer with teeth or not. *Atherinopsis.*

11. MENIDIA Bonaparte.

Menidia Bonaparte, Fauna Italica 1836 (*menidia*).
? *Chirostoma* Swainson, Fishes 1839, 243 (*humboldtianum*).
Argyrea Dekay, New York Fauna, Fishes, 141, 1842 (*notata*).
Atherinoides Bleeker, Verhand., Batav. Genootsch. Japan, XX, 40, 1853 (*vomerina*).
? *Atherinichthys* Bleeker, l. c., 40 (*humboldtianum*).
? *Heterognathus* Girard, Proc. Ac. Nat. Sci. Phila., 1854, 198 (*humboldtianum*).
? *Lethestole* Jordan & Evermann, Bull. U. S. Nat. Mus. 47, 792, 1896 (*estor*).
Eslopsarum Jordan & Evermann, Check List Fishes, 330, 1896 (*jordani*).

If only the long jawed forms of *Chirostoma* of Mexico were considered, they could readily be generically distinguished from *Menidia*. But Meek has shown that while some species have a projecting lower jaw, others have the jaws equal and still others have the upper jaw projecting. These, according to Meek, intergrade to such an extent that no generic dividing line can be drawn between Mexican species. Inasmuch as the short jawed forms appear to be true *Menidias* it is a question whether the genus *Chirostoma* should not be united with *Menidia*.

Smitt and Fowler have made out that *Menidia laticlava* is synonymous with *A. regius*. Steindachner on the other hand found that they are generically distinct.

a. Head 3.66–4.5 in the length; depth 4–4.2; D. vi–viiii–i, 10; A. i, 13–14; Lat. line 75–80. 21. *mauleana*.

aa. Head 5.5–6; depth 6.6–7; D. viii, 10; A. i, 18; Lat. line 86. 22. *laticlava*.

aaa.[1] Head 5.5; depth 5.5; D. vii, 9; A. i, 16; Lat. line 68–70; eye a little more than 4.4 in head. 23. *hatcheri* sp. nov.

aaaa. Head 5; depth 8.5; D. vi–viii, 10; A. i, 18–i, 20; Lat. line 100; eye 3–5 in head, a conspicuous silvery lateral band; each scale of the back with one or more dots; origin of spinous dorsal over tips of ventrals. *patagoniensis* sp. nov.

21. MENIDIA MAULEANA (Steindachner).

Chirostoma mauleanum Steindachner, Ann. Naturh. Hofmus. V, II, 1896, 213 (Pichi Laguna, a branch of Lake Llanquihue); id., Zool. Jahrb. 1898, Suppl. IV, 313.

This species is known only from the types.

[1] Hatcher collected three small specimens, probably at Sandy Point (Punta Arenas), Straits of Magellan.

22. Menidia laticlava (Cuvier & Valenciennes).

Atherina laticlava Cuvier & Valenciennes, Hist. Nat. Poiss. X, 473, 1835 (Valparaiso; Laguna de la Taguatugua); Guichenot, in Gay Hist. Chile, Zool. II, 252, 1848, and plate iv, fig. 1, 1854.

Atherinichthys laticlava Günther, Cat. Fish. Brit. Mus. III, 402 (Valparaiso; Falkland Islands; Port Louis); Cunningham, Trans. Linn. Soc. London, XXVII, 471, 1871 (Punta Arenas, Port Famine, Port Gallant, all on Str. of Magellan); Vaillant, Miss. Scient. Cap Horn, Poiss. C. 22, 1888 (Rio Pesca); Perugia, Ann. Mus. Civ. Stor. Nat. di Genova, Ser. 23, X (xxx), 620, 1891 (mouth of the Rio Negro); Delfin, Catalogo Peces Chile, 46, 1901.

23. Menidia hatcheri spec. nov.

(Plate XXXVII, Fig. 4.)

Type: A single specimen 219 mm. to base of caudal. Lake Pueyrredon. Elongate; head 5½; depth 5½; D. VI–I, 9; A. I, 16; lat. line 68–70. Snout 3.75 in head, eye 4.4, 1.6 in interorbital; mouth small, the lower jaw included when closed; snout and premaxillary equal to length of eye; snout and maxillary equals length of snout, the maxillary not reaching the eye. Teeth in narrow bands in each jaw, persistent, those of the outer jaw slightly enlarged; no teeth on vomer.

Spinous dorsal nearer caudal than tip of snout, its origin about over tip of ventrals, its tip over anus; origin of second dorsal over second fourth of anal, its tip not reaching tip of anal. Caudal widely forked; anal emarginate, its last ray a little longer than eye, considerably longer than some of the preceding rays, its longest anterior ray equal to half the distance between tip of snout and origin of pectoral, equal to length of ventrals; ventrals reaching very little more than half way to anal; pectorals short, about 6½ in the length, reaching half way to middle of ventrals.

A silvery lateral band, margined with plumbeous above; each scale of head and body with a band of chromatophores along the margin, those of the back more numerous than below; all the fins dusky, the membranes being densely pigmented. Scales cycloid.

12. ATHERINOPSIS Girard.

Atherinopsis Girard, Proc. Ac. Nat. Sci., Phila. VII, 1854, 134 (*californiensis*).

Basilichthys Girard, Proc. Acad. Nat. Sci. Phila. VII, 1854, 198, and U. S. Naval and Astronomical Expedition, 238, 1855 (*microlepidotus*).

The genus *Basilichthys* is distinguished from *Atherinopsis* solely on the relative length of the jaws. Girard says: "The genus *Basilichthys* will be characterized by the protrusion of the upper jaw beyond the lower." It was based on *Atherina microlepidota*, by Steindachner considered a synonym of the *Atherina regia* of Humboldt.

The *Atherinopsis* is defined as having "no palatine teeth, with both jaws equal, and the snout more or less rounded." Until specimens can be directly compared, the genus *Basilichthys* may be united with *Atherinopsis*.

There is but a single species of this genus in Patagonian waters. If, as Steindachner thinks, the species is confined to the Pacific coast from Valparaiso northward, the reference to this species south of that point may belong to *Menidia laticlava*.

24. ATHERINOPSIS REGIUS (Humboldt).

Atherina regia Humboldt, Rec. Observ. Zool. Anat. Comp. II, 187, 1835 (Callao; Lima); Cuvier and Valenciennes, Hist. Nat. Poiss, X, 474, 1835.

?*Atherinichthys regia* Smitt, Bihang Svenska Akad. Handl. XXVI, Afd. IV, No. 5, 93, pl. ix, figs. 30–31, 1898 (in part).

Atherinopsis regius Steindachner, Dk. Ak. Wiss. Wien, LXXII, 39, 1902 (Rio Tambo, South Peru).

?*Atherinopsis regia* Hatcher, these reports, Vol. I, 280, 1903 (Inlet of the Gallegos river).

Atherina microlepidota Jenyns, Voy. Beagle, Fishes, IV, 68, pl. xvi, fig. 1, 1842 (Valparaiso); Guichenot, Gay Hist. Chile, Zool. II, 253, 1848.

Basilichthys microlepidotus Girard, Proc. Acad. Nat. Sci. Phila. VII, 1854, 198; id. U. S. Nav. and Astron. Exped., 238, plate xxx, figs. 8 and 9, 1855 (Valparaiso; Mapocho, a tributary of the Maypu); Evermann & Kendall, Proc. U. S. Nat. Mus. XXXI, 1906, 97 (Lakes Nahuel Huapi and Traful; Nirihuahay, tributary of Rio Limay).

Atherinichthys microlepidota Günther, Cat. Fish. Brit. Mus. III, 403, 1861; Kner, Novara, Fisch. 222, 1869; ?Perugia, Ann. del Mus. Civ. di Stor. Nat. Ser. 2*a*, X (XXX), 620, 1891 (Mouth of the Rio Negro); Berg, Ann. Mus. Nac. Buenos Aires, IV, 28, 1895; Delfin, Catalogo Peces Chile, 47, 1901.

Atherina laticlava Cope, Proc. Am. Philos. Soc. XVII, 1878, 44 (Callao).

Habitat: (?Montevideo to) Valparaiso and northward in salt and fresh water.

No specimens of this species were collected by Hatcher. He says of it: "One species, *Atherinopsis regia*, of particularly fine flavor, is especially common at certain seasons along the east coast. So abundant were these fish in the inlet of the Gallegos river for several days during the spring of 1898 that on one occasion they were brought in great schools by the incoming tide and left stranded in such quantities on the shingle bed of the north coast that, for a distance of twelve miles, or over, the beach extending from North Gallegos to two or three miles above Killik Aike, the shingle was covered to an average width of ten yards and to the depth often of several inches with dead fish."

Suborder Percomorphi.

Cope, Proc. A. A. A. S., 1871, Indianapolis, 341.

A dominant group of fishes of fresh and especially of salt water.

Ventrals thoracic, with a spine and 4 or 5 rays; lower pharyngeals usually separate; gills 4, a slit behind the fourth; nares double on each side; scales ctenoid; post temporal slender, divided at tip and not coössified with skull; bones of jaw distinct; pectoral actinosts normal; vertebræ 24–40.

Family VIII. *SERRANIDÆ.*

Maxillary usually not sheathed by the preorbital (sheathed in Patagonian species); anterior vertebræ without transverse processes; all or most of the ribs inserted on the transverse processes when these are developed; anal spines 3; pseudobranchiæ well developed; vomer with teeth; lateral line extending to base of caudal; anal shorter than dorsal; head not everywhere covered with rough scales; second suborbital with an internal lamina supporting the globe of the eye; entopterygoid present; six or seven branchiostegals.

Of this widely distributed family, whose species are chiefly marine, two genera with five species are found in South American fresh waters. Two of the species are found in Patagonia, two others are confined to Central Chili, and the fifth is found near Buenos Aires. The genera may be distinguished by the following characters:

a. Two dorsals; pectoral asymmetrical, upper rays longest; ventrals below or a little behind base of pectoral. Tongue smooth; scales ciliate; vertebræ 33–35.
  b. Maxillary with supplemental bone; ventral below posterior edge of base of pectoral; palatine toothed; scales small. *Percichthys.*
  bb. Maxillary without supplemental bone; ventral a little behind base of pectoral; palatine toothless; scales larger. *Percilia.*

13. PERCICHTHYS Girard.

Percichthys Girard, Proc. Acad. Nat. Sci. Phila., VII, 1854, 197 and U. S. Naval and Astronom. Exped. 230, 1855. (*trucha.*)
Type: Perca trucha Cuvier & Valenciennes.

Species of Percichthys.

a. Depth less than length of head.
  b. Sides of head and body usually spotted; highest dorsal spine less than half the length of head in adult; scales 8 to 10–59 to 67–22 to 25. 25. *trucha.*
  bb. Sides of head plain; highest dorsal spine more than half the length of head in the adult; lateral line 66–70. 26. *vinciguerræ.*
aa. Depth equals length of head.
  c. Maxillary extending to below anterior border of eye; 10–13 spines on lower border of preopercle. Scales 10 or 11–54 to 58–19 or 20. 27. *melanops.*
  cc. Maxillary extending a little beyond the margin of the eye; 4–7 spines on the lower limb of preopercle; scales 8–66 to 72–23. 28. *altipinnis.*

25. Percichthys trucha (Cuvier & Valenciennes).

(Plate XXXVI, Fig. 3, and Plate XXXVII, Fig. 2.)

Perca trucha Cuvier & Valenciennes, Hist. Nat. Poiss. IX, 429, 1833 (Rio Negro, Chile); Guichenot, in Gay, Hist. Chile, Zool. II, 146, 1848 (Chile); id. Atl. Ichthiol. I, v, fig. 1, 1854.
Percichthys trucha Girard, Proc. Ac. Nat. Sci. Phila. VII, 1854, p. 197, and U. S. Naval and Astronom. Exped. II, 230, 1855; Günther, Cat. Fish. Brit. Mus. I, 61; Jordan & Eigenmann, Bull. U. S. Fish. Com. VIII, 427, 1890 (Santiago and Curico, Chili); Boulenger, Mem. Soc. Sc. Chile, IV, 10, 1894; id. Cat. Fish. Brit. Mus. I, 119, 1895;

Steindachner, Zool. Jahrb. 1898, Suppl. IV, Zweites Heft, 281 (Pichi-Laguna, an arm of Lake Llanquihue at Puerto Montt); Delfin, Catalogo Peces Chile, 58, 1901; Evermann & Kendall, Proc. U. S. Nat. Mus. XXXI, 1901, 100 (Rio Negro; Rio Limay; Lake Nahuel Huapi; Lake Traful).

Perca lævis Jenyns, Zool. Beagle, Fishes I, pl. i, 1842 (Rio Santa Cruz).

Fish Com. VIII, 428, 1890; Perugia, Ann. del Mus. Civ. Stor. Nat. Genova, Ser. 2*a*, X (XXX) 609, 1891 (Tierra del Fuego; Laguna del Rio Negro; Rio Santa Cruz).

Percichthys chilensis Girard, Proc. Acad. Nat. Sci. Phila., VII, 1854, 197; id., U. S. Naval and Astron. Exped. 231, pl. xxix, figs. 1–4, 1855 (Rio de Maypu, near Santiago, Chili); Philippi, Mon. Berl. Acad. 1866, 708.

Habitat: Rio Negro and Valparaiso and southward. Four specimens were taken by Hatcher in the Rio Santa Cruz; the locality of seven others is not indicated.

The following description is based on these specimens and on 12 specimens from Santiago and Curico, Chili.

Body elongate, deepest below first dorsal spine; maxillary reaching to below pupil, or little beyond anterior border of eye, $2\frac{4}{5}$ to 3 in head. Maxillary and mandibular teeth in similar bands, broadest in front and tapering backwards; teeth on vomer in a triangular patch; palatine bands of teeth much longer than those on vomer, separated from the latter, and placed almost at right angles to them. Head covered with scales forward to the anterior nostril, a short linear naked area, always present, at or near the base of the supraoccipital keel. Scales on cheeks in twelve to fifteen irregular series; scales on opercle as large as those on body, in about six series. Eye large, $1\frac{2}{5}$ to $1\frac{3}{5}$ in snout, 5 to $5\frac{3}{5}$ in head, 1 to $1\frac{1}{2}$ in interorbital space. Mouth terminal or subterminal, the lower jaw slightly included. Profile straight or very slightly concave from tip of occipital process to premaxillary process, thence abruptly decurved.

Preorbital with strong teeth directed downward and backward, strongest in young examples, largest near posterior angle of maxillary; entire vertical margin of preopercle with fine teeth, largest below; lower mar-

gin of preopercle with larger, wider-set teeth, the anterior ones directed forward; posterior half of free edge of interopercle and lower half of subopercle with very fine teeth, which become more or less obsolete with age; opercle with a strong spine and a blunt or rounded point above it.

Gill-rakers short, chubby, about two-thirds the length of the pupil, 6 + 13; inner side of the gill-rakers covered with short, stout teeth.

Distance of first dorsal spine from tip of snout, $2\frac{3}{5}$ in length of body. First dorsal spine less than half the length of the second, the second from one-half to two-thirds length of the third spine, which is the highest, $2\frac{1}{5}$ in the head in adult, $1\frac{3}{5}$ in young, the spines decreasing in height to the ninth; the spinous and soft dorsals connected. Caudal in the young slightly emarginate, the upper part truncate, lower rounded. First anal spine inserted under second dorsal ray, the spines graduated, the second strongest, highest ray 2–2¼ in head. Ventral inserted below the base of lower pectoral rays, the second divided ray longest, $2\frac{1}{5}$ to $1\frac{4}{5}$ in head. Pectoral 2 to $1\frac{4}{5}$ in head.

Scales of body of about uniform size, becoming very much smaller on breast and top of head. Scales strongly ctenoid on sides.

Small scales on the caudal membrane at its basal third. Anal and dorsal without scales.

Color olivaceous yellow, with peppery black dots, aggregated in spots on the back; the scales along base of dorsal and the upper half of caudal peduncle with a brownish spot at their base, spots forming more or less regular longitudinal lines; membrane of soft dorsal with minute brownish dots, aggregated in places to form rather large spots. Membrane of caudal dusky; anal with brownish dots along the middle of the membranes; pectorals and ventrals with similar, but fewer, spots. Head 3½–$3\frac{3}{5}$ in length, to base of caudal; depth 4 to $4\frac{2}{5}$; D. IX–XI, 11 or 12; A. III, 8–10. Scales 9–59 to 67–17. This species reaches a length of 480 mm.

26. Percichthys vinciguerræ Perugia.

(Plate XXXVII, Fig. 3.)

Percichthys vinciguerræ Perugia, Ann. del Mus. Civ. Stor. Nat. Genova, Ser. 2*a*, X (XXX), 610, 1891 (Rio Santa Cruz); Boulenger, Cat. Fishes, I, 120, 1895.

Through the courtesy of Dr. R. Gestro I have received one of the

types of *Percichthys vinciguerræ* Perugia and also a specimen of nearly the same size of *P. lævis* = *trucha*. The species is very closely allied if not identical with *trucha*. The characters on which Perugia laid stress as distinguishing this species are not present in the type sent me. Other characters which readily distinguish this specimen are different according to Perugia, in other specimens of *vinciguerræ*. The only characters distinguishing the type of *vinciguerræ* sent from the specimen of *trucha* of nearly equal size are the following:

a. Head and sides plain in color; depth $4\frac{3}{5}$ in length to caudal; lat. l. 70 (about); highest dorsal spine more than half length of head. *vinciguerræ*.

aa. Sides of head, above line back from angle of mouth, and sides of body spotted; depth 4 in the length; lat. l. 65; highest dorsal spine less than half length of head. *trucha*.

The extent of the maxillary made use of by Perugia is not diagnostic. Taking the distance from tip of snout to end of maxillary with dividers and comparing it with distance of tip of snout from eye, it is found that in the three specimens of *trucha* collected by Hatcher and the *trucha* and *vinciguerræ* collected by the Italian expedition:

1. Hatcher specimen; maxillary reaches middle of eye.
2. Hatcher specimen; maxillary reaches to anterior margin of pupil.
3. Hatcher specimen; maxillary reaches to anterior margin of pupil.
4. *P. lævis* collected by Italian expedition; maxillary reaches posterior margin of pupil.
5. *P. vinciguerræ*; maxillary reaches to middle of pupil.

The number of spines on the lower limb of the left preopercle of the five specimens are respectively 8, 11, 8, 11, 11.

The scales in the lateral line are 61, 65, 59, 65, 70.

The greatest depth of body in the length to base of caudal is respectively 4, 4, 4, 4, $4\frac{3}{5}$, the specimen of *vinciguerræ* being distinctly more slender than the others. I am inclined to think that the depth "$3\frac{3}{4}$" of Perugia must be a misprint for $4\frac{3}{4}$.

In a specimen collected by Hatcher with a length of 210 mm. the highest dorsal spine is equal to half the length of the head; in a specimen 160 mm. long it is equal to the head less the opercle.

Elongate slender, deepest in space between base of ventrals and first dorsal spine; maxillary reaching to below middle of pupil, 3 in the head; teeth as in *trucha*; squamation of head similar to that of *trucha* but the occipital crest and parietals striate and naked (in this specimen only?);

scales of cheek irregular in size, those near edge the smallest; opercular scales as large as those on body. Eye $1\frac{4}{5}$ in snout, $1\frac{2}{5}$ in interorbital, $6\frac{1}{3}$ in head; mouth terminal, jaws equal, profile slightly concave from middle of occipital process to tip of maxillary process.

Preorbital serrate; vertical limb of preopercle finely serrate, lower limb of preopercle with strong antrorse spines, more or less aggregated in groups of two or three.

Opercular spine as in *trucha*, subopercle and interopercle finely serrate.

Gill-rakers about $\frac{4}{5}$ the diameter of pupil, 9 + 13.

Distance of first dorsal spine from tip of snout $2\frac{5}{7}$ in the length; fourth dorsal spine highest, more than half length of head; caudal emarginate; ventrals $1\frac{3}{5}$ in head, pectorals $1\frac{3}{4}$. Scales as in *trucha*.

Sides yellowish *without spots* aside from the chromatophores giving the darker color of the back; left dorsal and caudal very faintly spotted, other fins plain.

D. x, 11 or 12; A. iii, 9; scales $7\frac{1}{2}$ to 9–66 to 70–18.

27. Percichthys melanops (Girard).

(Plate XXXVI, Figs. 2, 2*a* and 2*b*.)

Percichthys melanops Girard, Proc. Acad. Nat. Sci. Phila. VII, 1854, 197 (Rio de Maypu, Chili); id., U. S. Nav. and Astron. Exped. 233, pl. xxx, figs. 1–5, 1855 (Rio de Maypu, Chili); Günther, Cat. Fish. Brit. Mus. I, 61, 1859; Jordan & Eigenmann, Bull. U. S. Fish Com. VIII, 428, 1890; Boulenger, Mem. Soc. Sc. Chile IV, 13, 1894; id., Cat. Fish. Brit. Mus. I, 120, 1895; Delfin, Catalogo Peces de Chile, (Rio Maipo, Central Chili; Colima).

Percosoma melanops Gill, Proc. Acad. Nat. Sci. Phila. 51, 1861.

Perca pocha Philippi, Arch. Wiegm. 1863, 210 (Santiago, Chili).

Percichthys pocha Jordan & Eigenmann, Bull. U. S. Fish. Com. VIII, 428, 1890 (Curico, Chili).

The southernmost record for this species is Curico, Chili, about 100 miles north of the source of the Neuquen on the Pacific slope.

Body ovate, deepest below first dorsal spine. Maxillary reaching scarcely to vertical from anterior margin of orbit, 3 in head. Teeth of lower jaw in a band widest near tip, and tapering to a single series behind, some of the lateral teeth longer than the others; teeth of upper jaw in a

broader band, those of the sides not in a single series, teeth all about equal; teeth on vomer in a very narrow, crescent-shaped patch; those on palatines in a band much narrower and shorter than that on the vomer. Mouth oblique, the jaws subequal, the lower slightly included. Head scaled forward to the anterior nostril; scales on cheek in about eight series, those on opercle about as large as those on body, in about six series. Profile straight, from anterior margin of orbit to tip of occipital crest, rounded in front and behind. Eye 1½ in snout, 4½ to 5 in head; interorbital area a little wider than eye. Preorbital minutely serrate, the serræ weaker than in *P. trucha*. Preopercle with minute teeth on its vertical border, the teeth near the angle sometimes very much enlarged, sometimes little enlarged, more numerous than in *P. trucha*; serration of the subopercle and preopercle scarcely visible; opercular spine placed higher than in *P. trucha*, its tip sometimes incompletely two or three parted; a bluntish projection on opercle above the spine. Gill-rakers very short, about equal to one-third diameter of eye, 6 + 11. Distance of first dorsal spine from snout $2\frac{3}{7}$ to $2\frac{4}{7}$ in the length. Height of dorsal spines variable, the first always less than half as high as the second, the third or fourth dorsal spine highest, 2 to 3 in head, the spines decreasing in height to the ninth; spinous and soft dorsal connected. Caudal truncate when spread out, emarginate when closed. Anal inserted below the beginning of the soft dorsal, its spines graduated, the second thickest; highest ray about half as long as the head; ventral $1\frac{6}{7}$ in head; pectoral 1½ to $1\frac{6}{7}$ in head.

Scales on the body of about equal size, less strongly ctenoid than in *P. trucha*, reduced on breast and head. Lateral line much more strongly curved than in *P. trucha*.

Color brownish, golden-yellow below, everywhere with brownish dots; those on the lower half of the body scattered with usually a light (blue?) center, a dusky spot at the base of each scale on the sides; all the fins dusky, with reddish brown dots; those on the base of the soft dorsal sometimes aggregated into spots. Head 3 to 3¼ in length to base of caudal; depth 3 to 3¼; D. x, 11 or 12; A. III, 9 or 10. Scales 10 or 11–54 to 58–19 or 20.

This species reaches a length of 180 mm.

28. Percichthys altipinnis Regan.

(Plate XXXVII, Fig. 1.)

Percichthys altipinnis Regan, Revue Suisse de Zoologie 13, 390, 1905 (Rio Colorado, Buenos Aires). Dorsal x–xi–i, 11; Anal iii, 8 or 9; scales 8–66 to 72–23.

Depth 3.5–3.66; head 3.6–3.75; eye 5–5.33 in the head, interorbital 4.33–4.66 in the same. Maxillary extending a little beyond the margin of the eye; preorbital finely serrate; vertical limb of preopercle finely serrate, the angle armed with 2 or 3 spines and with 4–7 antrorse spines on the lower limb; a strong spine at the opercle; 3–5 spines at the clavicle above the base of pectoral; supraclavicle fine serrate; third dorsal spine longest, measuring $\frac{4}{5}$ of the length of the head; second anal spine longest, $\frac{2}{5}$ of the length of the head. Olivaceous.

This species is known only from the types. It is the most northern of the eastern species.

14. PERCILIA Girard.

Percilia Girard, Proc. Acad. Nat. Sci. Phila., VII, 1854, 197 and U. S. Naval and Astron. Exped. 235 (*gillissi*).

Type: Percilia gillissi Girard.

This genus does not belong to the tropical American fauna. Nor has it been taken in Patagonian waters. Its affinities are Patagonian. Its southernmost recorded habitat is the Rio Itata directly opposite the source of the Neuquen, the northern source of the Rio Negro. I have not seen the species and have drawn on Boulenger's account of it.

29. Percilia gillissi Girard.

(Plate XXXVI, Fig. 1).

Percilia gillissi Girard, Proc. Acad. Nat. Sci. Phila., VII, 197, 1854 (Rio de Maypo); Girard, U. S. Nav. and Astron. Exped. 236, pl. xxix, figs. 5–9, 1856 (Rio de Maypo); Günther, Cat. Fish. Brit. Mus. I, 255, 1859; Boulenger, Mem. Soc. Sc. Chile, IV, 15, 1894; Boulenger, Cat. Fish. Brit. Mus. I, 121, 1895 (Itata); Delfin, Catalogo Peces Chile 59, 1901 (Maipu and Itata; Pline).

Perca segethi Philippi, Wiegm., Arch. 1863, 211 (Santiago, Chili).

Percilia gracilis Philippi, Mb. Akad. Wiss. Berl. 1866, 708 (Rio Reine,

Santiago, Chili); Jordan & Eigenmann, Bull. U. S. Nat. Mus. VIII, 430, 1890.

Habitat: Chili from Itata to Valparaiso.

D. VIII–IX, I, 10–11. A. III, 8–10. Scales 4 or 5–36 to 40–9 to 11; lat. line 1, 33–35.

Depth of body 5¼ to 4 times in total length, length of head 3⅓ to 3½ times. Snout slightly overlapping lower jaw, as long as the diameter of the eye, which is 3½ to 4 times in length of head, and a little exceeds interorbital width; maxillary reaching to below anterior border of eye, the width of its distal extremity about ⅓ diameter of eye; head naked above, cheeks and opercles scaly. Gill-rakers very short, 10 to 12 on lower part of anterior arch. Dorsal originating behind vertical of axilla, spinous portion once and a half to once and two thirds as long as second; third or fourth dorsal spine longest, ⅗ to ⅔ length of head, and longer than longest soft rays. Pectoral ⅔ to ¾ length of head. Second anal spine longest. Caudal truncate. Brownish above, the scales often edged with black; yellowish beneath; young with eight or nine more or less distinct dark cross-bars and the caudal barred with blackish; lips, border of gill-membranes, pectoral and border of dorsal fins red.

This species reaches a length of 95 mm.

THE ARCHIPLATA–ARCHHELENIS THEORY.

I. Statement of the Theory.

In volume IV, page 319, *et seq.*, of these Reports, Ortmann discusses von Ihering's Archiplata-Archhelenis theory from the standpoint of marine invertebrate fossils. Inasmuch as the evidence for this theory is mainly derived from the fresh-water fauna, I propose to discuss the application of the distribution of the fresh-water fishes of tropical America to this theory. Before entering into the details I shall outline the theory in von Ihering's own words,[1] culled from his resumé in Science (new series, XII, 857–864, 1900.)

"The study of the fresh-water fauna, and especially of the Unionidæ of South America, gave me as a practical result the separation of the two sub-regions 'Archiplata' and 'Archamazonia.' The first contains Chili, Argentina, Uruguay and Southern Brazil, the second central and Northern Brazil (Archibrazil) and Guyana, Venezuela, etc. (Archiguyana). Archiplata contains numerous genera of Mollusca, Crustacea, etc., that are com-

[1] Ortmann has misread von Ihering in putting the line separating Archiplata and Archhelenis in the Amazon valley. Ortmann says :

"Archiamazonas or Archhelenis were separated completely from Archiplata by a broad stretch of sea, which extended across the present continent, where is now the valley of the Amazon River, the Cordilleras not being yet formed, and thus a broad communication existed between what is now the Atlantic and Pacific Oceans." * * *

Ortmann has been led into this mistake no doubt by the probable northward extension of Archiplata along the present line of the Cordilleras to central Peru, where Archiplata most nearly approached, not Archhelenis, but the Archipelago of the northern Cordilleras more nearly associated with Archhelenis.

"Communication was possible in a certain degree between the shores of Archiplata and Archiamazonas. This fact is most plainly seen in the presence of Navidad fossils in corresponding deposits of northern Peru; the Navidad beds were apparently deposited near the northwestern extremity of Archiplata, and the Payta Tumbez beds near the southwestern extremity of Archiamazonas: at these places we have probably these two continents at their points of nearest approach to each other, and an exchange of marine forms may have been possible. The exchange, however, was rendered more difficult by climatic conditions, and especially, although possible in a certain degree between the Ecuadorian and the Chilian province, it was hard for the Caribbean and Ecuadorian fauna to migrate further south, into the Patagonian region." Ortmann, l. c.

Ortmann includes the greater part of Archhelenis, *i. e.*, Archibrazil, in Archiplata.

mon to Chili and the La Plata district, such as *Unio*, *Chilina*, *Parastacus*, *Æglea*, etc., including many species and even their parasites (*Temnocephala*). which are identical on both sides of the Andes. This contrasts sharply with the Archamazonian fauna, as tropical genera extend to Rio Plata and Rio Negro, which are completely wanting in Chili and Peru. In Ecuador, however, the Cordilleras form no such zoögeographical division, due certainly to differences in the geological history of both parts of the Andes. * * * These facts point out that the invasion of the Archamazonian element into Archiplata is quite a recent one. The intrusion of the Archamazonian element is Pliocene or post-Tertiary, and the Andes formed a barrier insurmountable to fresh-water crabs and mussels as well as to fishes, chelonians and alligators.

"It is evident that the two faunal elements of South America correspond to geographical districts which were separated by the ocean during the greater part of the Tertiary. The intermixture of the two elements, and especially the intrusion of Bolivian ants, land snails, etc., in Eastern Brazil is by no means finished, but is a fact which we observe to-day. * * *

"In relation to the ancient connection of Africa and Archamazonia I have given arguments (1890) in favor of a Mesozoic 'archiatlantic continent,' which existed during the earlier Tertiary.

"At first because of some paleontological facts noted by Schlosser, I believed that this continent could have transmitted Eocene mammals from South Africa to Europe, an idea now defended by Ameghino and Osborn; but in 1893 I modified my opinion and set forth the hypothesis that no Eocene placental mammals had existed either in Archamazonia or in Æthiopian Africa. The ancient continent uniting Archamazonia with Africa I named Archiatlantica in 1890, using in 1892 the term Helenis, and in 1893 that of Archhelenis, with the purpose of preventing confusion with the 'Atlantis' a hypothetical land bridge between South Europe and Central America proposed by Unger.

"The intimate relations between the fresh-water faunas of Africa and Brazil, and the colossal difference which exists between the fresh-water faunas of Archamazonia and Archiplata, prove that both territories during the greater part of the Tertiary were separated quite as completely as the two Americas. In this case the mammalian fauna of Patagonia may have reached Ecuador or Columbia by means of the upheaval of the Andes, but not Brazil, and both Brazil and the Æthiopian region may have been

without mammals and especially placental mammals, during the Eocene. When, toward the close of the Eocene this land-bridge was submerged, there already existed many types that have been conserved until our time. * * * Archamazonia, after the loss of the connection with Africa, consisted of Archiguyana and Archibrazil. * * * While the distribution of the existing types of mammals is a result of changes in geography during Tertiary time, the most fundamental facts in the distribution of the fresh-water fauna dates from the Mesozoic epoch. The fresh-water fauna of Chili preserved such a remnant of the Cretaceous fauna almost intact, and even the connection between the two Americas has not at all modified the South American fresh-water fauna. * * * There is a further difference in the distribution of mammals and fresh-water mussels. The former migrate on land-bridges in most directions, the fresh-water fauna generally in only one, due to the opportunity given by the currents. Thus although there was an invasion of Cyprinid fishes into Africa there was no corresponding emigration of Æthiopian types. * * *

"The fresh-water fauna is not only older but also much more conservative than the distribution of mammals. One of the most striking examples of this is given by the history of Africa. While the characteristic mammals are Neogene immigrants, and Lydekker proceeds quite correctly in making Africa an annex only of the Holarctic region, thus establishing his Arctogæa, with relation to the fresh-water fauna, Africa is a part of South America, somewhat modified by the Neogene invasion of Cyprinid fishes. If as regards mammals Africa belongs to Arctogæa, with relation to the fresh-water fauna it belongs to the Archhelenic region."

It is seen from the above that von Ihering divides South America into two distinct faunal areas, that he attributes the division to an ancient separation of the continent into Archiplata and Archamazonia, that he places the separating sea north of Uruguay and that he divides Archhelenis into Archiguyana and Archibrazil by the eastern Amazon valley. Derby has objected to the Uruguayan sea because there is no geological evidence for it. The fresh-water fishes demand a more southern line on the east than northern Uruguay, and, considering the fresh-water fishes only, there is no hesitation in placing the line in the La Plata-Paraguay valley and allowing it to extend to the north-west corner of Archiplata, wherever that may have been, probably in central Peru.

II. Ichthyogeographical regions.

America, south of the Tropic of Cancer, contains four (or five) distinct faunas. These faunas are the Transition, the Mexican, the South American and the Patagonian. Only the last two are intimately concerned with the Archiplata-Archhelenis theory.

The northernmost, or Transition Fauna, is characterized largely by intrusive elements from both the north and the south. It is found on the Atlantic slope from the tropic to the Isthmus of Tehuantepec and on the Pacific slope of this isthmus. It is of comparatively recent origin and not an independent fauna but a mixture of the advance guards of the North American and South American faunas.

The Mexican fauna is unique, and occupies a narrow strip including the valley of the city of Mexico and the Lerma basin, draining to the west, and the Rio San Juan, a tributary of the Panuco, draining to the east. While containing intrusive elements from the north, it contains none from the south, and its fauna is so distinct from either that there is slight hesitation in considering it as equivalent to the North American, South American and Patagonian faunas. It is a very old fauna, but has at no time influenced the South American fauna.

The third, the South American Fauna, is sharply divisible into the Brazilian and Andean. The Brazilian occupies the rivers from Southern Mexico to Buenos Aires and from the Atlantic to the Pacific, exclusive of the high Andes and Chili. This fauna is the richest in species in the world. From this region about 10 per cent. of all the known fishes have been recorded. The Andean, from 3,000 to 5,000 feet and over above sea level, while possessing some forms in common with the Brazilian, is quite distinct. The species inhabiting this region, while derived from the Brazilian fauna, have become so far modified that they would cause surprise if found at Manaos; those of the lower portions of the Pacific slope would not.

The Patagonian fauna, in distinct contrast to the South American, is one of the poorest in the world. It occupies the Rio Negro basin and everything lying south of it and a line joining it with Valparaiso. Its fauna is distinct from the Brazilian and has been considered in detail, pp. 227–292.

For convenience these faunal areas may be enumerated as the following "regions" of unequal value.

1. Transition.
2. Mexican.
3. Brazilian.
4. Andean.[1]
5. Patagonian.

III. The Transition Region.

While there are absolutely no North American intrusive elements in South America, a number of Mississippi Valley forms have reached as far as the Isthmus of Tehuantepec; only a *Lepisosteus*, *Carpiodes meridionalis* and possibly *Aplodinotus grunniens* extend farther.

On the Atlantic slope the North American fauna gradually gives place to or shades into the tropical fauna between the Rio Grande on the north and the Isthmus of Tehuantepec on the south. The Rio Grande fauna is distinctly northern, that of the Papaloapam on the south is as distinctly tropical, although the former contains a few southern elements and the latter a few northern ones. On the western slope, the southern element makes its appearance farther south than on the eastern and is separated from the northern realm by the Mexican fauna. The Mexican and Transition faunas have recently been made the subject of profound and exhaustive study by Meek and I can not do better than to summarize his results.

In this discussion the *Petromyzonidæ*, *Bagrinæ*, *Catostomidæ* and *Cyprinidæ*, being unquestionably derivatives from the north, are credited to the north, although some of the genera are peculiar to the Mexican or Transition regions. For similar reasons members of the *Cichlidæ*, *Characidæ*, *Pimelodinæ et al.* are considered South American, although some of the genera are peculiar to or dominant in Mexico and Central America. *Agonostomus* and the *Pœciliidæ*, which are dominant in Mexico, Central America and the West Indies, are considered Transitional, although they extend both into North America and South America.

In the Rio Grande basin on the boundary of the United States there are known to occur sixty-one species of fishes. Of this number three species, *Astyanax mexicanus*, *Cichlasoma pavonaceum* and *Herichthys cyanoguttatum*, are distinctly tropical, belonging as they do to Central or South American genera; forty-four are distinctly northern, and of the remainder, two are tropical Gobies also found on the American Gulf coast, and eleven

[1] The Titicacan basin probably should constitute a "region" distinct from the Andean north of Titicaca.

are *Pœciliidæ*, some of them distinctly northern and some distinctly southern, but none of them causing any surprise.

Farther south, near the tropic on the Atlantic side, is the basin of the Rio Panuco. Nearly half of its fauna, 15 species out of a total of 32, belongs to the northern fauna. Five species are distinctly tropical. In the following list of species from this river the northern forms are marked with an N, the southern with an S and the Mexican with an M, the transition forms with a T. Marine derivatives are marked Me. The Rio Panuco is on the same degree of latitude north of the equator that the Parahyba is south. The Parahyba harbors over 50 species, all of them equatorial; of the 32 found in the Panuco less than 16 per cent. are equatorial.

THE PANUCO SYSTEM (after Meek).

N *Lepisosteus osseus* (Linnæus).
N *Lepisosteus tristœchus* (Bloch & Schneider).
N *Ictalurus furcatus* (Le Sueur).
N *Ictalurus punctatus* (Rafinesque).
N *Ameiurus australis* Meek.
N *Ameiurus mexicanus* Meek.
N *Carpiodes tumidus* Baird & Girard.
N *Carpiodes labiosus* Meek.
N *Algansea tincella* (Cuvier & Valenciennes).
N *Hybognathus rasconis* (Jordan & Snyder).
N *Aztecula mexicana* Meek.
N *Notropis forlonensis* Meek.
S *Astyanax mexicanus* (Filippi).
N *Dorosoma exile* Jordan & Gilbert.
N *Signalosa mexicana* (Günther).
N *Fundulus heteroclitus* (Linnæus).
T *Cyprinodon eximius* Girard.
T *Gambusia affinis* (Baird & Girard).
M *Goodea toweri* Meek.
M *Goodea atripinnis* Jordan.
M *Platypœcilus variatus* Meek.
T *Pœcilia latipunctata* Meek.
T *Pœcilia sphenops* Cuvier & Valenciennes.
T *Molienesia latipinna* Le Sueur.

T *Xiphophorus montezumæ* Jordan & Snyder.
Me *Pomadasys templei* Meek.
S *Cichlasoma steindachneri* Jordan & Snyder.
S *Cichlasoma bartoni* (Bean).
S *Herichthys cyanoguttatum* (Baird & Girard).
S *Neotroplus carpintis* Jordan & Snyder.[1]
T *Philypnus dormitor* (Lacépède).
T *Chonophorus taiasica* (Lichtenstein).

This number of species was taken from near tide level to an elevation of almost 2000 feet.

On the Pacific slope the Rio Presidio, a short, insignificant stream, at Mazatlan is near the tropic. North of it no South American elements are found.

Its fishes are:

T *Pœcilia butleri* Jordan.
T *Pœcilia presidionis* Jordan & Culver.
Me *Siphostoma starksi* Jordan & Culver.
Me *Thyrina crystallina* Jordan & Culver.
T *Agonostomus monticola* Bancroft.
S *Cichlasoma beani* (Jordan).
T *Philypnus dormitor* (Lacépède).
T *Dormitator maculata* (Bloch).
T *Eleotris pictus* Kner & Steindachner.
T *Chonophorus taiasicus* (Lichtenstein).
Me *Achirus mazatlanus* (Steindachner).
Me *Achirus fonsecensis* (Günther).

Only *Cichlasoma beani* is distinctly tropical American. *Agonostomus* is Central American; the rest are types that would cause no surprise anywhere in a coastwise stream between the United States and South America.

The Rio Presidio, the Rio Mezquital to the south and the Rio Yaqui to the north, are on the slope of the Sierra Madre opposed to the slope drained by the Rio Grande. Confining ourselves for the present to the consideration of replacement of the northern by the southern fauna, we shall return to a comparison of their fauna with that of the Rio Grande.

[1] This species is included in the synonymy of the one preceding it in the systematic part of this report.

The Rio Mezquital south of the Presidio contains:

N *Ameiurus pricei* (Rutter).
N *Pantosteus plebeius*(Baird & Girard).
*N *Moxostoma austrinum* Bean.
N *Hybognathus episcopus* (Girard).
N *Leuciscus nigrescens* (Girard).
N *Notropis ornatus* (Girard).
M *Characodon garmani* Jordan & Evermann.
*M *Characodon furcidens* Jordan & Gilbert.
T *Cyprinodon latifasciatus* Garman.
*M *Chirostoma mezquital* Meek.
N *Etheostoma pottsii* (Girard).

As Meek points out, all but three of these species (marked *) belong to the Rio Grande basin and were probably captured from it. There are no distinctly South American elements in this river system as far as examined; it belongs to the north. But no collections have been made below the Mexican plateau and the tropical elements would naturally occur in the lowlands.

Skipping the Rio Grande de Santiago and its tributary the Lerma, whose basin embraces the greater part of the Mexican plateau, the Rio Balsas belongs distinctly to the transition zone containing *Tetragonopterus mexicanus* and *Cichlasoma istlarius* as (S) South American intrusives; *Istlarius*, *Aztecula* and *Notropis* as (N) North American intrusives, the first two of which have become generically distinct from their North American relatives and might therefore be classed as transition genera. The rest are transition genera (T) with the one exception of the Mexican *Goodea*.

This river is almost equal in size to the Lerma. It contains only about one-fourth as many fishes. Its basin is larger than the basin of the Panuco. It was fished from about 1400 feet to 6000 feet in elevation. In this area the number of species is less than half the number found in the Panuco.

N *Istlarius balsanus* Jordan & Snyder.
N *Aztecula vittata* (Girard).
N *Notropis boucardi* (Günther).
S *Astyanax mexicanus* (Philippi).
T *Gambusia gracilis* (Heckel).
M *Goodea whitei* Meek.

T *Platypœcilus nelsoni* Meek.
T *Pœcilia sphenops* Cuvier & Valenciennes.
T *Melaniris balsanus* Meek.
T *Agonostomus monticola* (Bancroft).
S *Cichlasoma istlanum* (Jordan & Snyder).
T *Chonophorus taiasicus* (Lichtenstein).

Near the Isthmus of Tehuantepec, on the Atlantic side, is the basin of the Papaloapam with the following species. In this river the northern element has approached the vanishing point, while the southern element is increasing. Collections were made from tide level to an elevation of about 3500 feet.

Me *Galeichthys aguadulce* Meek.
S *Rhamdia oaxacæ* Meek.
S *Rhamdia brachyptera* (Cope).
N *Carpiodes meridionalis* (Günther).
S *Astyanax mexicanus* (Filippi).
S *Astyanax æneus* (Günther).
S *Hemigrammus compressus* Meek.
N *Dorosoma anale* Meek.
N *Dorosoma exile* Jordan & Gilbert.
N *Signalosa mexicana* (Günther).
T *Cynodonichthys tenuis* Meek.
T *Pseudoxiphophorus bimaculatus* (Heckel).
T *Gambusia bonita* Meek.
T *Paragambusia nicaraguensis* (Günther).
T *Belonesox belizanus* Kner.
T *Platypœcilus maculatus* Günther.
T *Heterandria lutzi* Meek.
T *Pœcilia sphenops* Cuvier & Valenciennes.
T *Xiphophorus helleri* Heckel.
Me *Tylosurus marinus* (Walbaum).
Me *Menidia lisa* Meek.
T *Agonostomus monticola* (Bancroft).
Me *Centropomus mexicanus* Bocourt.
Me *Pomadasys starri* Meek.
Me *Pomadasys templei* Meek.
S *Cichlasoma salvini* (Günther).

S *Cichlasoma hedricki* Meek.
S *Cichlasoma parma* (Günther).
S *Cichlasoma eigenmanni* Meek.
S *Cichlasoma melanurum* (Günther).
S *Cichlasoma nebulifer* (Günther).
S *Thorichthys helleri* (Steindachner).
S *Thorichthys ellioti* Meek.
T *Philypnus dormitor* (Lacépède).
T *Dormitator maculatus* (Bloch).
T *Chonophorus taiasicus* (Lichtenstein).
Me *Achirus fasciatus* (Lacépède).

Only four out of the total of thirty-seven species are northern, while thirteen are distinctly tropical, of which the genera *Cichlasoma* and *Thorichthys* are largely middle American.

The list may be contrasted with the list of the combined Geronimo and Verde, directly across the headwaters of the Papaloapam and emptying into the Pacific. They were fished near tide water and at an elevation of nearly 5000 feet.

S *Astyanax æneus* (Günther).
T *Fundulus oxacæ* Meek.
T *Gambusia fasciata* Meek.
T *Anableps dovii* Gill.
T *Heterandria lutzi* Meek.
T *Pœcilia sphenops* Cuvier & Valenciennes.
Me *Mugil cephalus* Linnæus.
S *Cichlasoma evermanni* Meek.
T *Philypnus dormitor* (Lacépède.).

Of these, but two are South American, the rest are transitional.

The tropical element has reached farther north on the Atlantic side than on the Pacific, or in any cross section of the country there are more South American elements in the former than in the latter. None of the South American types have reached the plateau of Mexico. They skirt along the coastal plain on both slopes to an elevation of perhaps 2000 feet and in the Rio Grande basin to an elevation of even 3000 feet.

IV. The Mexican Region.

North of the Rio Balsas, and therefore north of the transition zone is the Rio Grande de Santiago. It is the largest river of the Pacific slope within the tropics or between the Rio Colorado and Tierra del Fuego. It is also by far the richest in species, the Rio Balsas coming next in size and but little further south containing but 12 species as compared with the 48 of the Rio Grande de Santiago. Many of the species of this region (*Chirostoma*) are indirect derivatives from the sea. The only fish in this, the largest Pacific slope river, that suggests South America, is *Cichlasoma beani*, and this occurs only near the coast. Its contact with North America is shown by such genera as *Lampetra*, *Ameiurus*, *Moxostoma*, *Algansea*, *Notropis* and *Hybopsis*.

This basin above the falls separating the coastal section from the Mexican plateau, together with the Valley of Mexico and the headwaters of the San Juan, a tributary of the Panuco, which rises in the Mexican plateau, harbors a fauna that is distinct from both the fauna of North America and that of South America or even southern Mexico. Of this Meek says: "From the area which includes the valley of Mexico, the headwaters of the San Juan del Rio and the Lerma basin, there are at present fifty-four species of fishes known (inclusive of coastal plain species), only two of which, *Moxostoma austrinum* Bean and *Aztecula vittata* (Girard) [to these should be added *Cichlasoma beani*] have been taken in any other river basin. These fifty-four species belong to twenty-one genera, eight of which are peculiar to this region." Three of the other genera are confined to the neighborhood and have probably emigrated from it, six are northern genera, of which only one extends farther south than this area. "The Lerma river system is far from being thoroughly explored, but apparently its fishes are quite as distinct and characteristic as if the fauna were insular."

The relation of each species in the following list to the northern (N), southern (S), or Marine (Me), faunas, whether peculiarly Mexican (M) or belonging to the coastal plain (C), is indicated by the respective symbols.

N *Lampetra spadicea* Bean.
N *Ameiurus dugesi* Bean.
N *Moxostoma austrinum* Bean.
N *Xystrosus popoche* Jordan & Snyder.
N *Algansea tincella* (Cuvier & Valenciennes).
N *Algansea dugesi* Bean.

N *Algansea rubescens* Meek.
N *Algansea lacustris* Steindachner.
N *Falcula chapalæ* Jordan & Snyder.
N *Aztecula lermæ* Jordan & Snyder.
N *Notropis calientis* Jordan & Snyder.
N *Hybopsis altus* (Jordan).
M *Zoogoneticus cuitzeœnsis* (B. A. Bean).
M *Zoogoneticus dugesi* (Bean).
M *Zoogoneticus robustus* (Bean).
M *Zoogoneticus maculatus* Regan.
M *Zoogoneticus diazi* Meek.
M *Characodon multiradiatus* Meek.
M *Characodon eiseni* Rutter.
M *Characodon variatus* Bean.
M *Characodon lateralis* Günther.
M *Chapalichthys encaustus* (Jordan & Snyder).
T *Gambusia infans* Woolman.
M *Goodea luitpoldi* (Steindachner).
M *Goodea atripinnis* Jordan.
M *Skiffia multipunctata* (Pellegrin).
M *Skiffia lermæ* Meek.
M *Skiffia variegata* Meek.
M *Skiffia bilineata* (Bean).
T *Pœcilia occidentalis* (Baird & Girard).
M *Chirostoma jordani* Woolman.
M *Chirostoma arge* (Jordan & Snyder).
M *Chirostoma bartoni* Jordan & Evermann.
M *Chirostoma attenuatum* Meek.
M *Chirostoma labarcæ* Meek.
M *Chirostoma patzcuaro* Meek.
M *Chirostoma zirahuen* Meek.
M *Chirostoma humboldtianum* (Cuvier & Valenciennes).
M *Chirostoma chapalæ* Jordan & Snyder.
M *Chirostoma grandocule* Steindachner.
M *Chirostoma promelas* Jordan & Snyder.
M *Chirostoma sphyræna* Boulenger.
M *Chirostoma lucius* Jordan & Snyder.

M *Chirostoma lermæ* Boulenger.
M *Chirostoma ocotlanæ* Jordan & Snyder.
M *Chirostoma estor* Jordan.
CT *Agonostomus monticola* (Bancroft).
CS *Cichlasoma beani* (Jordan).

It is evident from a glance at the letters showing the relationship of these species that the Mexican fauna has not been influenced by the South American fauna. Nor has it influenced in any way the South American fauna.

V. The Andean Region.

The Andean Region includes the high Andes on both slopes from Venezuela and Colombia to Chili.

It is poor in species at any given point, but some of the genera have a large number of local adaptations or species. This region is distinctly marked off into three provinces.

1. The Northern includes the high lands of northern Peru, Ecuador, Colombia and Venezuela. This is the richest in species and distinguished by the genera *Arges*, *Cyclopium*, *Prenadilla* and the high development of *Chætostomus*. Its fauna is largely an ancient derivative from the low-land fresh-water fauna of Archiguiana.

2. The Titicacan, including the basin of Titicaca and neighboring streams, and possibly the land-locked basins of Bolivia, concerning which nothing is known, is distinguished by the genus *Orestias* and the absence of the genera distinguishing the Northern province. Its fauna is largely an ancient derivative from the ocean.

3. The Southern is the poorest in species, characterized by the absence of everything but a few species of *Pygidium*, a genus which extends the entire length of the Andean Region.

Concerning the physical features of the Titicacan province Agassiz says (Bull. Mus. Comp. Zool. III, No. 11, 1875):

"In fact, the geography of the whole of the west coast of the Andes to the north of Chili seems to point to a former condition of things such as we now find on the west coast of Chili. The plains to the southward of Santiago, bounded by the coast range to the westward, and the Andes to the east, gradually pass to the condition of the coast now prevailing at Conception Bay, and south of it — the coast range forming the archipelago, the Andes forming the coast range, and the plains of the more

northern regions becoming changed to bays; the immense basins succeeding each other towards the north which form the so-called Desert of Atacama, the nitrate-beds, the llanos of the coast, the pampas of Peru, through which the rivers flowing to the west have cut deep valleys with more or less marked terraces, showing the different periods of ascent in the elevation of the continent. These plains are everywhere found either between a coast range and the base of the eastern talus of the Andes, or extending from the summit of the shore terrace, if we may so call it, generally at a height of from 1200 to 3000 feet, sloping to the second terrace, with its base at an average height of from 6000–7000 feet, and then followed by a second and third more or less indistinct terrace until we reach the main elevated plateau or basin which lies between the eastern and western slope of the Andes. All these basins show more or less distinctly the trace of their former marine origin, so that, if we are to judge from the presence of strictly marine forms, the successive terraces developed on a magnificent scale on the west coast of the Andes, with the interlying basins, we have a fair presumption that the elevation of the Andes to their present height has taken place at a comparatively recent date, and during their upheaval the present nitrate district and saline deposits were left as large lagoons during a considerable period, to judge from the great thickness of the deposits found within their basins, all denoting the presence of a comparatively quiet inland sea.

"Lake Titicaca itself must have, within a comparatively very recent geological period, formed quite an inland sea. The terraces of its former shores are everywhere most distinctly to be traced, showing that its water-level must have had an elevation of 300 or 400 feet at least higher than its present level. This alone would send its shores far to the north in the direction of Pucara, forming a narrow arm reaching up to S. Rosa. Lake Arapa is probably only an outlier of the ancient lake, as well as several of the small lakes, now at a considerable distance from the west shore. The immense plain of Cabanillas, extending north beyond Lampa to Juliaca, only 100 or 120 feet above the lake at its highest point, was one sheet of water. The terraces of the former shores are still very distinctly seen. The eastern shores did not probably differ greatly from the present outline, though the peninsula of Achacache was probably an island. The bay of Puno must have been connected with the plains of Llave, and those back of Juli; while from the lower lake, back of Aygache,

the lake formed huge inlets or deep bays, now represented only by the nearly dry river-beds flowing into the lake at Aygache, Corilla and Guajui. The sluggish Desaguadero must have been a strait of considerable width, with large islands; and this long lake, connecting Lake Titicaca with Lake Aullagas, must have equalled in extent the upper lake, the upper lake, at that time, extending across the Isthmus of Yunguyo, leaving the Peninsula of Copacabana, as a large island, connected with the lower lake by a broad pass between the hills to the west of Copacabana, and those to the west of Yunguyo. The plains, now laid bare at the northern and western shores of Lake Titicaca, give us an excellent idea of the appearance the whole basin of the lake would present if entirely dry. The number of lakes and basins, great and small, which formerly covered the elevated plateau of the Andes, must have been very great; but we now find only here and there a small sheet of water. The former lakes are only represented by the more or less extensive pampas, forming basins at great altitudes, showing plainly that the whole of this district is receiving a much smaller waterfall than in former times, but probably not within historic times, if we take into consideration the position of some of the most ancient ruins of Bolivia (at Tiahuanaco), which are only about 75 feet above the present level of the lake."[1]

The area to which Lake Titicaca belongs probably remained separate from Ecuador until long after the latter was colonized from Archiguiana, and the Brazilian fauna did not gain access to the Titicacan region until after the elevation of the lake had become too great for most of the Brazilian types of fishes.

I give below a list of the species of the Northern and Titicacan provinces with the localities from which they are recorded. The Northern province is characterized by several genera, some of them undoubted derivatives of the neighboring lowlands marked "/" and by others on the western slope derived from the sea marked "Me." *Rhamdia* and *Pygidium* have a wide distribution. The Titicacan province is characterized by the extravagant genus *Orestias*, which has developed from a *Fundulus*-like species received when the lake was still an arm of the sea.[2]

[1] See also page 372.

[2] The crustacean fauna is even more evidently of marine origin. The genus *Orchestia*, with its seven Titicacan species, is still preëminently a marine genus.

1. *Northern.*

/ *Rhamdia pentlandi* Cuvier & Valenciennes: Monterico, Tullumayo, Rio Huambo.
Pygidium rivulatum (Cuvier & Valenciennes): Ucayale.
Pygidium pœyanum (Cope): Arequiba, Peru.
Pygidium meridæ (Regan): Merida and Rio Albirregas, near Merida, Venezuela.
Pygidium tænia (Kner): western slopes of Peru.
Pygidium laticeps (Kner): western slopes of Peru.
Pygidium knerii (Steindachner): Canelos and Rio Zamora, Peru.
Pygidium eigenmanni (Boulenger): Cumbaca.
Pygidium dispar Tschudi: eastern slope of Peru at an altitude of 14,000 feet.
Pygidium nigromaculatum (Boulenger): Colombia.
Pygidium taczanowskii (Steindachner): Rio de Huambo; Rio de Tortora.
Pygidium quechuorum (Steindachner): Arequipa, Peru.
/ *Eremophilus mutisii* Humboldt: Bogota.
/ *Chætostomus*—all (14) species of this genus.
/ *Arges*—all (15) species of this genus (to an elevation of at least 10,700 feet).
/ *Cyclopium*—all (4) species of this genus.
/ *Astroblepus grixalvii* Humboldt: Popayan, Rio Cauca.
/ *Creagrutus*—all species.
Me *Protistius semotilus* Cope:[1] Peruvian Andes at an elevation of 12,000 feet).
Me *Gastropterus archæus* Cope:[1] Arequiba, at an elevation of 7,500 feet.
Me *Oreogobius rosenbergii* Boulenger: Paramba, northwest Ecuador, 3,500 feet.

2. *Titicacan.*

Pygidium rivulatum (Cuvier & Valenciennes).
/ *Ancistrus montana* (Regan): eastern Andes of Bolivia.
/ *Ancistrus triformis* (Cuvier & Valenciennes): eastern Andes of Peru and Bolivia.
Orestias—all (11) species of this genus.

From the Southern Province there are known only a very few species of *Pygidium.*

[1] These two genera occur in the latitude of Titicaca, south of the other species. I am not sure that they do not belong to the Titicacan province.

VI. The Brazilian Region.

The Brazilian region is divisible into several conspicuously marked provinces; the Central American, including the area from Veragua to the Isthmus of Tehuantepec; the Pacific, including the Pacific slope from Panama to Peru; the Amazonian, including all the lowlands drained by the Amazons; the southeastern, including the streams from Cape San Roque to Santos and the Trinidad Province. Less marked provinces are the La Platan, the Guianan and the Magdalenan, the latter including the Chagres. All of these provinces are distinguished from the Amazonian chiefly by negative characters. The number of peculiar genera varies greatly in the different provinces.

The question of the character of the different provinces is largely a question of what Amazonian types are absent. We shall take up these provinces in detail emphasizing the Central American, Pacific and Magdalenan, as these are of chief interest in discussing later the origin of the Pacific slope fauna, and the East Brazilian and Guianian, because these are the ones principally concerned in the Archiplata-Archhelenis theory.

Manaos is the centre of the great Brazilian region and the variety of the fauna of any province, other things being equal, varies inversely with its distance from Manaos. The Magdalena and the San Francisco at opposite sides of Manaos have essentially the same types of fishes.

1. *The Central American Province.*

This province extends from the Isthmus of Darien to the Isthmus of Tehuantepec.

The most comprehensive account of the Central American province has been given by Günther (An Account of the Fishes of the States of Central America, Trans. Zool. Soc. VI, 1866). Recently Miller has made a detailed study of the Motagua basin. This province will amply repay further study.[1] Günther has shown that this province is distinguished from the South American by the absence of most South American families. A few *Pimelodinæ* of the Nematognathi and a few forms of the Tetragonopterinæ and of the Characinæ are all there is of the one thousand species of the Ostariophysiæ found in the Brazilian region. The genera *Cichlasoma* and *Æquidens* are dominant in all the streams.

[1] The proof of this had been read before Regan's Pisces of the Biol. Cent. Amer. appeared.

Günther has shown that the short and separated water courses are for the most part inhabited by local adaptations or species peculiar to each water system, or two or three of the neighboring systems. For instance, all but two or three of the inhabitants of Lake Peten are peculiar to this small lake.

For this reason he has been able to divide this province into the following subprovinces :

A. Fresh waters north of the Lakes of Managua and Nicaragua, emptying into the Pacific. From this subdivision he recorded 22 species, nearly all of them confined to this region. Only 4 of these species extend north as far as the Isthmus of Tehuantepec. Eight are South American, one, *Lepisosteus*, is northern, nine are transitional or middle American and the rest are Marine.

B. The fresh waters north of the Lakes of Managua and Nicaragua, emptying into the Atlantic. From this subregion he recorded 28 species nearly all of which are peculiar. Eighteen are South American in their relationships. Only four species, *Pimelodus salvini*, *Belonesox belizanus*, *Xiphophorus helleri* and *Ameiurus meridionalis* (from the Usumacinta) are found north of the province; only the last is a northern intrusive. The Rio Motagua contains no North American elements. This subprovince also contains *Gymnotus carapo* and *Symbranchus marmoratus*, the South American species having the farthest range northward.

C. Lake Peten with 14 species, of which all but two were supposed to be peculiar.

D. Lake Managua with 6 species.

E. Lake Nicaragua with 9 species.

F. The fresh waters south of the Lakes of Managua and Nicaragua to the Isthmus of Darien. (The region about Panama is unmistakably South American, as distinct from Central American.)

2. *Pacific Province.*

The Pacific province includes all the fresh waters emptying into the Pacific from Panama to the southern boundary of Peru, except the headwaters above an elevation of about 3000 feet. It is a narrow strip, nowhere exceeding 200 kilometers in width, and in places less than 50 kilometers wide. North of 5° of south latitude it is abundantly supplied with rivers. South of this point the rivers become smaller and of less importance. The rivers are the Mamoni and Chepo in Panama, Rio San Juan

and Rio Patia Mira in Colombia, the Esmeralda, Daule, Guayas and Tumbey in Ecuador, and the Chia, Jequetepec, Santa, Rimac and others in Peru. None of those in Colombia have been examined, and but few of those in Peru.

The headwaters of these rivers are all near the headwaters of Atlantic slope streams. In northern Ecuador and in Peru they are separated by a high ridge. Of special interest are the San Juan and Patia. In northern Peru there are four main chains of the Cordilleras, besides the coast range. The valleys between these are occupied by large rivers, the Ucayale, Huallaga and Marañon, all ultimately draining into the Amazon. In Ecuador there are two very high chains with frequent cross-ridges dividing the longitudinal trough into parks or highland basins, some drained to the east and some to the west.

In Colombia there are again four chains. The eastern one divides towards the north, one branch sweeping around to the east toward Caracas and Trinidad, another branch extending to the coast west of Lake Maracaibo. Between this and the central chain flows the Magdalena which occupies much the same position in regard to the Cordilleras that the Ucayale or Huallaga occupies, but empties into the Caribbean Sea. Between the central and western Cordilleras flows the Cauca, a large tributary of the Magdalena. South of the Cauca the Rio Patia has cut through the western Cordilleras, its headwaters coming from the same trough in which the Cauca flows.

Of still higher interest is the trough between the western Cordillera and the coast or border Cordillera.

Sievers, p. 478, states that the west Cordillera of Ecuador is younger than the central Cordillera, and the coast range still younger. Its height varies from 800–1800 m. A longitudinal valley separates the coast range from the western Cordillera. In this flows the Atrato towards the north, emptying into the gulf of Darien and the San Juan towards the south, emptying into the Pacific Ocean. The water-shed separating the two scarcely reaches a height of 100 m. above sea-level, the distance of the height of land above their headwaters is naturally much less than this.[1] I shall return to these rivers again.

The fauna of this province, so far as known, is very poor. In con-

[1] A gentleman, for several years a missionary in Colombia, has informed me that the Indians of the Atrato have a legendary belief in a former interoceanic connection through the Atrato valley.

sidering it two things may be borne in mind: 1, that the province, while very long, is very narrow and contains no large river system, which is so necessary to develop or harbor a diverse fauna. The sources of the Paute, a tributary of the Marañon are only 60 km. from the bay of Guayaquil. In North America the large Colorado, Sacramento or Columbia basins of the Pacific slope contain fewer species of fishes than the unknown Beanblossom creek of the Mississippi basin: 2, that no river has been thoroughly explored and some of the principal ones, the San Juan and Patia for instance, not at all.

With very few exceptions, the species of this province belong to genera with a very wide distribution; on the Atlantic slope, all but one of these genera reach as far north as the Magdalena or Panama. Few of the species would have occasioned surprise if they had been discovered at Manaos. There are remarkably few peculiar genera, which indicates a comparatively recent separation from the Atlantic slope fauna. The species recorded from this province are listed below and marked "*" for species peculiar, "**" genus peculiar, "/" species found also in the Chagres or Magdalena, "Me" marine. Most of the species are recorded from Ecuador, few are found in Peru, and Colombia has not been explored.

/ *Rhamdia cinerascens* (Günther): Rio Daule; Rio Peripa; Guayaquil and Esmeraldas; Chagres.

/ *Rhamdia wagneri* (Günther): Atlantic and Pacific slope of Panama; Mamoni near Chepo.

/ *Pimelodus clarias* (Bloch): Rio Bayano—eastern slope to Buenos Aires.

/ *Pimelodella modesta* (Günther): Eastern Panama; Esmeraldas.

* *Pimelodella elongata* (Günther).

* *Pimelodella grisea* Regan: Durango; Sapayo and Vaqueria Rivers, in northwest Ecuador.

* *Pimelodella yuncensis* Steindachner: Pacasmayo.

** *Cetopsogiton occidentalis* (Steindachner): Guayaquil.

Species of *Pygidium*, *Arges*, *Cyclopium* and *Chætostomus* considered under the Andean Region may descend into this province.

* *Pygidium punctulatum* (Cuvier & Valenciennes): Callao.

* *Pygidium pardus* (Cope): Jequitepeque; Callao Bay.

* *Plecostomus spinosissimus* Steindachner: Guayaquil; Rio Vinces; Rio Daule.

* *Plecostomus festæ* Boulenger: Rio Vinces; Rio Peripa.

* *Hemiancistrus annectens* (Regan): St. Javier and Rio Durango, west Ecuador.
* *Hemiancistrus aspidolepis* (Günther): Pacific slope of Panama.
* *Chætostomus fischeri* Steindachner: Rio Mamoni near Chepo.
* *Chætostomus dermorhynchus* Boulenger: Rio Zamora; Rio Santiago; Rio Peripa; Rio Vinces.
* *Chætostomus microps* Günther: Western slope of Ecuador.
* *Loricaria jubata* Boulenger: St. Javier 60 feet; Rio Durango 350 feet.
* *Loricaria variegata* Steindachner: Mamoni.
/ *Loricaria uracantha* Kner & Steindachner: both slopes of Panama.
/ *Sturisoma panamensis* (Eigenmann & Eigenmann): Rio Magdalena; Pacific slope of Panama.
* *Sturisoma frenata* Boulenger: St. Javier 60 feet; Salidero 350 feet; Rio Durango 350 feet.
/ *Hoplias microlepis* (Günther): Rio Chagres; Rio Daule; Rio Vinces; Guayaquil.
** *Lebiasina bimaculata* Cuvier & Valenciennes: Callao; Rio Vinas; Lima; Remac; Eten.
* *Curimatus troschelii* Günther: Guayaquil; Rio Vinces.
/ *Curimatus magdalenæ* Steindachner: Magdalena; Mamoni.
* *Curimatus boulengeri* Eigenmann: Rio Vinces.
* *Prochilodus humeralis* Günther: Rio Peripa, western Ecuador.
* *Prochilodus caudofasciatus* Starks: Perene.
** *Saccodon wagneri* Kner & Steindachner: Ecuador.
** *Saccodon craniocephalum* Thominot: Rio Guayaquil.
* *Leporinus leschenaulti* Cuvier & Valenciennes: Guayaquil.
* *Piabucina astrigata* Regan.
** *Pseudochalceus lineatus* Kner: western slope of the Andes of Ecuador.
* *Astyanax festæ* (Boulenger): Rio Vinces and Mirador, Ecuador.
/ *Astyanax rutilus* (Jenyns): western Ecuador: Rio de la Plata to Mexico.
* *Astyanax simus* (Boulenger): western Ecuador.
Astyanax peruanus (Müller & Troschel): Rio Remac; Pacasmayo; Lake Amatitlan, Rio Eten and Payta, Peru.
* *Hemibrycon polyodon* (Günther): Guayaquil.
* *Brycon alburnus* Günther: Rio Peripa and Rio Vinces, western Ecuador.
/ *Brycon dentex* Günther: Esmeraldas and Rio Peripa to Lake Nicaragua and Rio Usumacinta.

/ *Brycon atrocaudatus* Kner: Magdalena; Paramba, western Ecuador, Payta and Eten, Peru.
? *Creagrutus peruanus* Steindachner: Monterico and Huambo, Peru.
/ *Creagrutus mülleri* Günther: Cauca; Canelos; Andes of western Ecuador.
* *Gasteropelecus maculatus* Steindachner: Mamoni.
/ *Luciocharax insculptus* Steindachner: Mamoni; Magdalena.
/ *Eigenmannia humboldtii* (Steindachner): Mamoni; Magdalena.
/ *Gymnotus æquilabiatus* Humboldt: Guayaquil; Magdalena.
/ *Symbranchus marmoratus* Bloch: Panama; entire eastern slope.
Me *Stolephorus poeyi* (Kner & Steindachner): Rio Bayano.
Me *Pristigaster effulgens* Regan: Rio Vaqueria.
Fundulus guatemalensis Günther: western Ecuador to Amatitlan and Guacalate.
* *Aplocheilus peruanus* Regan: Perim.
* *Pœcilia festæ* Boulenger: Hot Springs, S. Vicenta, Santa Elena, Ecuador.
Me *Tylosurus fluviatilis* Regan: Western Ecuador.
* Me *Centropomus atridorsalis* Regan: Rio Vagueria, near la Tola, N. W. Ecuador.
* *Æquidens sapayensis* Regan: Rio Sapayo, Ecuador.
* *Æquidens rivulata* (Günther): Rio Sapayo; Rio Peripa; Rio Vinces.
/ *Cichlasoma godmanii* Günther: west slope of Panama; Rio Cahabon, Atlantic slope.
* *Cichlasoma festæ* Boulenger: Rio Durango, Ecuador.
Me * *Awaous güntheri* Regan: western Ecuador.
Me * *Awaous transandeanus* Günther: western Ecuador.
Me * *Goboides peruanus* Steindachner.
Me * *Chasmodes maculipinna* Regan: Rio Durango.

Number of species, 65; number peculiar, 42; on Atlantic slope, 18 of which in Amazon, 3.

These are for the most part lowland species belonging to lowland genera, *i. e.*, not such as are found in mountain streams or that are likely to have reached the Pacific slope by crossing the high Andes. *Pygidium* and *Chætostomus* are exceptions to this. If all of the purely freshwater species could be transferred to Manaos or Tabatinga there are very few that would occasion surprise if taken in the collector's net.

3. *Magdalena Province.*

The fauna of the Rio Magdalena, as far as known, is of peculiar interest, in connection with the fauna of the Pacific Province. The Madalena basin is Y-shaped. The right (thick) arm and stem form the Rio Magdalena proper, draining the area between the eastern and central Andes of southern Colombia. The left arm of the Y is the Cauca, which drains the area between the central and the western Andes of Colombia. The central Andes appear to stop at the junction of the arms of the Y.

The Magdalena has an elevation of 1600 m. at San Augustin, 1000 m. at Timana and 400 m. at Neiva. There are rapids at the 5th degree of north latitude about Pescaderias. In its lower course it is a much-branched and divided stream. Its length is about 1350 km. and it drains 300,000 square kilometers. The Cauca at Popayan has an elevation of 1740 m. It is marked with rapids at Quilichao 1070 m., and again, below Cartago, 900 m., and between Antioquia and Caceres.

Nearly all that is known of the fauna of this river has been contributed by Steindachner in three papers, in which the following fresh-water species are enumerated (exclusive of mountain forms).

Species *, and genus **, peculiar to the Magdalena; species /, and genus //, peculiar to Magdalena, Panama and western slopes of Ecuador. A, also found in the Amazon.

* *Potamotrygon magdalenæ* Steindachner.
A *Pseudopimelodus zungaro* (Humboldt).
A *Rhamdia sebæ* (Cuvier & Valenciennes).
A *Pimelodus clarias* (Bloch).
* *Pimelodus grosskopfii* Steindachner.
A *Pseudoplatystoma fasciatum* (Linnæus).
A *Sorubim lima* (Bloch & Schneider).
* *Doras longipinnis* Steindachner.
Trachycorystes insignis (Steindachner).
Trachycorystes magdalenæ (Steindachner).
* *Ageneiosus caucanus* Steindachner.
A *Ageneiosus dentatus* Kner.
? *Pygidium*, probably several species in upper reaches of the rivers.
A *Hoplosternum thoracatum* Cuvier & Valenciennes.
A *Plecostomus emarginatus* Cuvier & Valenciennes.
* *Panaque cochliodon* (Steindachner).

* *Pterygoplichthys undecimalis* (Steindachner).
* *Loricaria filamentosa* Steindachner.
* *Loricaria magdalenæ* Steindachner.
/ *Sturisoma panamense* (Eigenmann & Eigenmann).
A *Hoplias malabaricus* (Bloch).
/ *Curimatus magdalenæ* Steindachner.
* *Curimatus mivartii* Steindachner.
A *Prochilodus rubrotæniatus* Schomburgk.
* *Prochilodus magdalenæ* Steindachner.
* *Prochilodus longirostris* Steindachner.
A *Leporinus eques* Steindachner.
* *Leporinus muyscarus* Steindachner.
A *Leporinus obtusidens* (Valenciennes).
A *Leporinus striatus* Kner.
A *Leporellus vittatus* (Cuvier & Valenciennes).
* *Cheirodon insignis* Steindachner.
A *Astyanax bimaculatus* (Linnæus).
/ *Astyanax rutilus* (Jenyns).
* *Astyanax caucanus* (Steindachner).
* *Brycon rubricauda* Steindachner.
/ *Brycon atricaudatus* (Kner).
* *Othonophanes labiatus* (Steindachner).
/ *Creagrutus mülleri* Günther. (Cauca and Ecuador).
* *Chalcinus magdalenæ* Steindachner.
* *Poeboides dayii* Steindachner.
Cynopotamus magdalenæ Steindachner. (Magdalena and Paraguay).
Salminus affinis Steindachner. (Magdalena and Ecuador).
** *Acestrocephalus anomalus* (Steindachner).
** *Gilbertolus alatus* (Steindachner).
// *Luciocharax insculptus* Steindachner.
A *Hypopomus brevirostris* Steindachner.
? / *Eigenmannia humboldtii* (Steindachner).
/ *Gymnotus æquilabiatus* Humboldt.
A *Synbranchus marmoratus* Bloch.
* *Rivulus elegans* Steindachner.
* *Girardinus caucanus* Steindachner.
Æquidens pulchrum (Gill). (Rio Chagres to Trinidad.)

* *Cichlasoma kraussii* Steindachner.
* *Geophagus steindachneri* Eigenmann & Hildebrandt.
/ *Geophagus crassilabris* Steindachner.

Undoubtedly this is but a small part of the fauna of this basin. As our knowledge stands at present, this basin lacks very largely those Amazonian genera that are also absent from the coastal plain of southeastern Brazil. See later List. Thirty per cent. of its known species are Amazonian.

4. *The Amazon Province.*

East of the Cordilleras, and therefore east of the Magdalena basin, is found the most extensive and intricate fresh water system in the world. It forms a network of rivers practically uninterrupted, extending from the mouth of the Orinoco through the Cassiquiare, Rio Branco, Rio Negro, Rio Madeira, Rio Guaporé, Rio Paraguay, Parana and La Plata to Buenos Aires, through 45° of latitude and from Para to within a few miles of the Pacific coast, through 30° of longitude at the equator.

The connection between the Orinoco and Branco through the Cassiquiare has been definitely known since Humboldt traversed it. The following is from the International Bureau of American Republics, "United States of Brazil," p. 79:

"Another remarkable phenomenon of the Paraguay is the mingling of its principal head waters with those of the affluents of the Amazon. An affluent of the Jauru River is sufficiently near the Guaporé River to be connected with the latter by a canal. The Aguapehy, another tributary of this river, is separated from the Alegre by a narrow isthmus 5 kilometers wide. In the eighteenth century an attempt was made to open up a canal here, and owing to the abundant rains a large canoe of 12 oars succeeded in passing from the one river to the other. One of the governors of the state also endeavored to open up a canal 10 kilometers long in another part of the isthmus, but on account of the small amount of trade it was never completed. This would connect Montevideo and Para by a continental waterway 8300 kilometers long. In the near future it is probable that railways will take the place of the canal. There are many places on the edge of the plateau, farther to the east, where a simple cut of a few meters would connect the tributaries of the Amazon with those of the Paraguay, transforming eastern Brazil into an island. There is a

space of but 100 meters between the Estivado, a small tributary of the Tapajoz, and the Tombador, which empties into the Cuyaba."

Cuyaba on the headwaters of the Paraguay is not more than 200 m. in elevation and the junction of the Cassiquiare with the Orinoco has an elevation of but 280 m. One could therefore traverse the 8300 kilometers by inland water without ever exceeding an elevation of 280 m.

The Amazon itself, where it leaves the Andes, has an elevation of but 180 m.; indeed nearly 60 per cent. of all South America consists of flat lowlands, drained by this system of rivers.

The Amazon draining more than 7,000,000 square kilometers, the La Plata about 3,100,000 and the Orinoco about 1,000,000, these rivers which as far as the fishes are concerned form a single system, drain an area 3⅔ times as large as the Mississippi basin.

The lowlands through which these main rivers flow are the youngest part of South America. The parts that first arose out of the sea and became populated with fresh-water fishes were probably two land areas. The one embraces the highlands of Guiana and Northern Brazil, the other the highlands of Brazil east of the Araguay and south of the falls of the Tapajos. In Tertiary times the Cordilleras arose out of the ocean on the west. The basins left as open seas between the three land areas later, in late Tertiary, became dry land, in part by elevation and in part by delta formation by the rivers coming from the surrounding land masses. The rivers coming from the Andes became stocked from the surrounding ocean and *later* from one of the older eastern land areas. *The main part of the later colonization very probably did not take place until the Andes had become an effective barrier to the distribution of fresh-water fishes.*

These interior rivers, chiefly the Amazons, colonized from the northeast and southeast became themselves the seat of unparalleled adaptive radiation and centers of distribution, as we shall see.

The Amazons are unequalled in richness and form a province distinct from the Orinoco and Guiana region to the north and the La Plata on the south. The La Plata basin is well distinguished from the Amazonian, but by negative characters only.[1]

[1] I insisted on this distinction in 1891. Perugia registered his "disgosto" with this scheme, because the fishes from the La Plata basin were nearly all Amazonian, as I had pointed out.

Neither the Orinoco nor the Paraguay contains any fishes that would cause the slightest surprise if they were found at Manaos or any other part of the Amazon. Every collection made in the Paraguay in recent years has brought to light more types hitherto considered Amazonian and has increased the number of genera and species that the two systems have in common. Very little is yet known of the Orinoco.

The list of Amazonian species is too long to give here. The Amazonian species have therefore been marked A in the general list of the species forming Part III of this report. They number about 700.

5. *The Guiana Province.*

The Guiana Province, including one of the oldest land masses, is drained by the Cachipur, Oyapoc, Cayenne, Mana, Maroni, Surinam, Corentine, Essequibo (Mazaruni, Cuyuni, Rupununi and other tributaries of the Essequibo), Demarara, Berbice, by the Orinoco and its eastern and southern tributaries, the Caroni, Caura, Ventuari and by the Rio Branco, and the northern tributaries of the Amazon east of the Branco.

The feature distinguishing this region is the known or reported connections between neighboring streams. The Cassiquiari connects the Orinoco with the Rio Negro. The Atabapo is said during the rainy season to be connected with the Guaina, and the Rupununi of the Essequibo basin with the Tacutu of the Rio Branco basin. It is said that the Essequibo is also connected with the Rio Trombetas through the Apini and the Oyapoc, Cachipur and Araguary with the tributaries of the Yari which empties into the Amazon.

The lower course of the Essequibo of British Guiana at least is connected with the lower Orinoco by natural canals, so that these form part of the Orinoco-Amazon-La Plata meshwork and contain the same types. The Eastern Guianas (French) have a less varied fauna.

The fauna of this region is of the greatest importance to theoretical chorology, since this is one of the two old land-masses, and since it was by a continuation of this area that South America is supposed to have been connected with Africa.

Our knowledge of the fish fauna of this region is derived from Müller & Troschel's account of the fishes of British Guiana; Bleeker's Silure de Surinam; Vaillant's notes on the fishes of French Guiana, and his account of the Berbice and the general work of Cuvier & Valenciennes, Günther, Eigenmann & Eigenmann, Regan and Pellegrin.

Unfortunately little is known of the fauna of the streams of the table land of Guiana, the region where the remnant of the original fauna may be expected to persist. Schomburgk's collections made in these streams were largely lost. He states that it was rich in species (over 30).

André ("A Naturalist in the Guianas," p. 205) says: "In fact the falls of Para [of the Caura] appear to constitute an effective barrier between distinct forms of river life," and that the fauna above the falls is different from that below.

The most promising field for scientific results, if not number of species, seems to me to be offered by the rivers of this region, which should be explored *above* and *below* falls that are impassable barriers for the ascent of fishes.

The rivers of this region, exclusive of the northern tributaries of the Amazon, concerning which not much is known, contain a total of about 298 recorded species. Of these about 60 per cent. are also found in the Amazon; as of these about 16 species are from the Rio Branco basin and not from the other streams and the Rio Branco belongs to the Amazon system, this number must be reduced by 16, which still leaves over 50 per cent. of the fauna identical with that of the Amazon.

List of Guiana Fishes with their Known Distribution.

In the following list the letter A indicates that the species has been recorded from the Amazon. L indicates that the species has been recorded from the La Plata, S that the genus is also found in the San Francisco, * that the species is peculiar to the province, ** that the genus is peculiar to the province.

6. *Trinidad Province.*

The fauna of Trinidad is of peculiar interest. Trinidad is an island off the delta of the Orinoco, approximately 40 by 50 miles. Its geographical affinity is with Venezuela rather than with Guiana. Its fresh-water fauna consists of three elements:

1. West Indian, 16+per cent. (about). This element consists chiefly of members of the Gobiidæ which enter fresh water throughout tropical America.

2. Amazonian, 33 per cent. This element consists, with few exceptions, of species ranging from the La Plata basin to Trinidad. The exceptions are found in the Amazon and Trinidad. All are marked A.

3. Autochthonous, 33 per cent. This element consists either of local adaptations, *, of genera with a very wide distribution, or of distinct genera marked **.

7. *Southeast or East Brazilian Plateau.*

The southern land-mass, Archamazona, the Brazilian plateau, is drained by the Tocantins, Rios San Francisco, Doce, Jequitinhonha, Parahyba and other coast streams and the upper tributaries and head-waters of the Parana. The rivers leave this mass over important falls. The Parana is part of the La Plata system, and as far as it may be considered, will be taken up with the La Plata.

This old land-mass was doubtless more extensive in the past. The isolated ranges or peaks in the territory west of the Araguay are the probable remnants of the formerly more extensive plateau. The falls in the Tocantins, Xingu, Tapajos and Madeira mark the probable northern and western boundary of this plateau. However, west of the Rio San Francisco, the streams all drain into the Amazon and their fauna could not have retained its original character. The western streams probably con-

tributed to the Amazonian fauna when the latter was formed and received in turn new Amazonian types.

The fauna of eastern Brazil differs much more from that of the Amazon than does that of the equally old Guiana. By eastern Brazil is here understood the northeastern part of this old land-mass, *i.e.*, the territory north of the Parana basin and between the eastern watershed of the Tocantins and the coast south from Cape San Roque to the Iguape. The entire territory has an average height of about 2,000 feet. North of the Parahyba it is in the form of two wide terraces, besides the coastal plain. The western terrace is occupied by the San Francisco basin; it is separated from the eastern narrower terrace by a series of Serras beginning with the Serra da Tuila, near the mouth of the San Francisco, and ending in the Serra do Espinhaco near Rio de Janeiro. In these Serras and the table-land or middle terrace to the east of them are the sources and middle courses of a number of rivers with a general west to east course.

This middle terrace is bordered on the east by the coast ranges extending from the Parahyba north. Through it all of the rivers of the region have broken their path and in it all of them have extensive falls.

These streams with the tributaries and localities where collections have been made are: (1) Rio Paraguassu, emptying at Bahia; (2) Rio de Contas; (3) Rios Jundiahe, Salsa, Pardo and Jequitinhonha (with its tributary Arrasuahy) emptying at Cannavierias; (4) Rio Mucury on which are located Porto Alegre and Santa Clara; (5) Rio de San Matheos; (6) Rio Doce and its tributary Rio San Antonio; (7) Rio Quenda, emptying at Santa Cruz; (8) Rio Itabapuana.

Farther south we have: (9) Rio Parahyba with its tributaries Piabanha, Pirahy, Muriahe, Pampa and Preto (Campos; Juiz de Fora; Mendez; Taubaté); (10) Macahe; (11) Rio de Janeiro; (12) Santos and Alto da Serra; (13) Iguape.

The Parahyba, Santos and Iguape are opposite to the Parana basin, all the others to the San Francisco. The trend of the Parahyba is different from that of the coastwise streams to the north of it. It flows first southwest, then northeast parallel with the coast range and between it and the Serra de Mantegueira. Von Ihering has suggested that the peculiar trend of the upper course of the Parahyba and some of its tributaries indicates that these were formerly tributaries of the Rio Tieté and were captured from it by the Parahyba. A partial comparison of the faunas of the Tieté and

Parahyba is possible, and will be given in the lists of species of this region.

The San Francisco, which occupies the western terrace and flows at right angles to the coastwise streams to near the 9th degree of latitude, where it also turns to the east, is the largest river. It has a length of 2000 km. and a basin of 652,000 square kilometers. Its origin is at an elevation of 1200 m., and about its headwaters "are some of the highest elevations in Brazil." It has an upper fall of 15 m. near Pirapora and a lower fall of 80 m. at Paulo Alfonso.

The fish fauna of this area has become known, first, through the work of Lütken, who has published an excellent account of the fishes of the Rio das Velhas, an upper tributary of the Rio San Francisco; second, through Steindachner, who has published accounts of the fishes of the coastwise streams, Steindachner basing his account on the very extensive collections made in the lower and upper courses of all the streams by Agassiz and his assistants, and through Eigenmann who has written on the fishes at Taubaté and the Rio Tieté.

The fauna of this area as a whole is distinguished by the absence of certain Amazonian forms. It is of increased interest because many genera absent from this area are found in the La Plata basin as well as in the Amazon basin, having evidently reached the La Plata through the interior waterway rather than from stream to stream along the coast.

8. *The San Franciscan Province.*

The Rio San Francisco being nearer the Amazonian Province has a larger proportion of Amazonian genera than the streams south of Bahia. Notably the Serrasalmoninæ and the Gymnotidæ, present in the San Francisco, are not recorded from the coast streams. It forms a faunal province distinct from the rest of the area to the east.

The following species have been recorded from the Rio San Francisco and its tributaries, the Rio Preto and Rio das Velhas, and the Rio Cipo, a tributary of the Velhas.

Explanation of Markings Used.

While this list shows many species and several peculiar genera as a whole, except for the absentees of many Amazonian genera and species, the fauna of this river does not differ more from that of the Amazon at Para than that of Para differs from the fauna of the Amazon at Tabatinga. Its fauna is much more like that of the Amazon than the fauna of the Colorado is like that of either the Rio Grande or the Lerma. A certain number of genera and species may always be expected to be peculiar.

Has this area a primitive fauna and did it serve as a center of distribution? If the theory of the population of the lowland streams from these ancient highlands is correct, we may reasonably infer that the genera now occupying this region are part of the ancient fauna. The San Francisco, occupying an isolated position in the very center of the old land mass, may serve as the basis of the discussion. Only the fresh-water families are of consequence in this discussion. The *Bunocephalidæ*, *Arapaimidæ*, *Lepidosirenidæ*, *Osteoglossidæ*, and *Argiidæ* are absent. Some of these, as the *Argiidæ*, might have developed from other forms that may have emigrated from this place, but not so the others. For these others the Brazilian plateau cannot have been the center of divergence. This is also the case with the *Serrasalmoninæ*, *Mylinæ* and *Gymnotidæ*. These are found in the San Francisco, but not in the coastwise streams east of the San Francisco basin. Have they in the past migrated from this place as a center? Possibly, but probably not, for while these are found to the west, north, and south of the San Francisco basin, they are not found to the east in the coastwise streams. It is, therefore, very probable that the San Francisco obtained these forms from the west, where they swarm and from where the south certainly obtained them, and that they have not yet succeeded in crossing the eastern boundary of the San Francisco. It is less probable that they migrated

from the San Francisco westward and not eastward. This applies with equal force to all other San Franciscan genera found in the Amazon and not in the coastwise streams.[1]

How is it with the genera *Pseudoplatystoma*, *Rhamdia*, *Rhamdella*, *Pimelodella*, *Pimelodus*, *Astyanax* and all the other genera of the San Francisco that have a wide distribution?[1] These probably belong to the original fauna, or had their origin in the San Francisco, or rather Brazilian plateau and have become distributed from it. Guiana has of course an equal claim on them; and there is no evidence that they have become distributed from the San Francisco rather than from Guiana.

There remain only the genera peculiar to the region, and, inasmuch as they have not become distributed they do not enter the question.

There is some evidence that part of the San Francisco fauna has been derived from the Amazon basin. This evidence consists of the fact that the San Francisco, which is nearer the Amazon basin, contains a larger number of Amazonian genera than the eastern streams, and in part, of the fact that the peculiarly lowland forms of the Amazon have not reached this province, and in part, of the presumption in favor of the Amazon because it has unquestionably acted as the center of distribution of many lowland forms that have reached the La Plata basin without entering the province under consideration.[2]

It is very probable that the San Francisco has contributed to the fauna to the south of it (see under the La Plata, etc.).

9. *The Coastal Province.*

The fauna of the second terrace and coastal plain from Bahia to Iguapé, whose rivers were described in a preceding section, shows a proportion of species peculiar to the region about equal to the proportion of peculiar species in the Pacific province, not considering marine derivatives and Pœciliidæ. There are eight peculiar genera, as compared with three in the Pacific province. This area contains a very much larger percentage of species that are also found in the Amazon than does the Magdalena.

Fifty genera present in the Amazon and La Plata basins are absent from the large streams between Bahia and Rio de Janeiro; over thirty of these are also absent from the San Francisco. They demonstrate their migra-

[1] See in the Guiana list those marked with an S.

[2] Mr. Haseman reports an open road for the passage of fishes from the Tocantins.

tion into the La Plata basin from the Amazon by some inland route, and that for the thirty and more genera at least, that are absent from this area and from the San Francisco, this territory could not have been the center of dispersal.

The fifty genera thus present in the Amazon and La Plata and absent from the coastal rivers exceed the total number of genera recorded from them.

The following genera found in the La Plata and Amazon have not been found in the coastwise streams. Those not recorded from the Magdalena are marked +; those not in the San Francisco ×.

× + *Bunocephalus*,
× + *Dysichthys*,
Pimelodus,
× + *Luciopimelodus*,
Pseudoplatystoma,
× + *Paulesca*,
× *Sorubim*,
? *Doras*,
+ *Oxydoras*,
+ *Centromochlus*,
+ *Stegophilus*,
× *Cetopsis*,
× *Ageneiosus*,
× + *Hoplosternum*,
× + *Hemiodontichthys*,
× + *Sturisoma*,
× + *Hypoptopoma*,
× + *Pyrrhulina*,
× + *Psectrogaster*,
+ *Curimatella*,
× + *Anodus*,
+ *Parodon*,
+ *Hemiodus*,
× + *Anisitsia*,
× + *Nannostomus*,
Anostomus,
+ *Charax*,
Leporellus,
× + *Holoshesthes*,
× + *Odontostilbe*,
Cheirodon,
× + *Aphyocharax*,
+ *Hemigrammus*,
× + *Gasteropelecus*,
Chalcinus,
× + *Piabucus*,
× + *Pygopristis*,
+ *Pygocentrus*,
+ *Serrasalmo*,
× + *Piaractus*,
× + *Metynnis*,
+ *Myleus*,
× + *Colossoma*,
× + *Mylossoma*,
× + *Charax*,
× + *Roestes*,
Rœboides,
Cynopotamus,
Salminus,
+ *Acestrorhynchus*,
Eigenmannia,
Gymnotus,
+ *Giton*,
× *Æquidens*,
× + *Biotodoma*,
× + *Cichlosoma*.

This area is also characterized by positive features, for we have the genera *Steindachneria*, *Pogonopoma*, *Wertheimeria*, *Hemipsilichthys*, *Delturus*, *Parotocinclus*, *Deuterodon*, *Henochilus*, *Harttia*, *Hollandichthys*, *Typhlobagrus*, *Cœlurichthys*, *Kronichthys*, peculiar to this province.

In the number of peculiar genera this province differs more from the Amazon than does that across the Andes in Eucador and Peru (see p. 312) and if the degree of difference is a criterion, it is an older fauna.

List of Species With Their Known Distribution.

In the following list:

A indicates that the species has been recorded from the Amazon.

L indicates that the species has been recorded from the La Plata, including Rio Grande do Sul.

* that the species is peculiar to this province.

** that the genus is peculiar to this province.

All the observations on the San Francisco basin as a possible center of distribution apply with equal force on the coastal province.

There are two facts that deserve emphasis: First at Taubaté, in the State of São Paulo on the Rio Parahyba, fossil fishes have been found in bituminous shales. The definite geological horizon of these rocks has not been determined and they contain no other fossils. These fossils belong, according to Smith Woodward, to the genera *Arius*, a genus now very abundant along the coasts of tropical America and entering fresh water; *Tetragonopterus*, or its ally *Astyanax*, still abundant in the Parahyba; *Percichthys*, now confined to the Patagonian region, and *Acara*, a Cichlid. Von Ihering contends that the *Percichthys* is not a member of the *Serranidæ* to which *Percichthys* belongs, but is a *Cichlid*, and Jordan makes a new genus *Eobrycon* of the fossil *Tetragonopterus*.

Von Ihering is inclined to the opinion that the shales were deposited during the Tertiary in a lake more than 120 km. long, occupying the valley of the Parahyba from the Serra de Mantaqueira to that of Bocaina.

Second, while there are many genera in the Amazon and the La Plata not found in eastern Brazil, there are also a number of species in the La Plata basin and eastern Brazil that have not been found in the Amazon. These are enumerated in the list of species of the coastwise streams and indicate that there has been a certain amount of migration between the La Plata and this region. The possible means of communication is indicated in the description of the Parahyba.

10. *The La Plata Province.*

Of the streams draining toward the south nothing is known ichthyologically of the Uruguay and very little of the upper Parana, while the Paraguay, owing to the work of Natterer, Ternetz and Anisits, is one of the best known regions of South America.

The Paraguay is a lowland stream, the elevation at its sources at Cuyaba being but 200 m. At Corumba it has an elevation of 140 m., at Puerto Pachero 100 m., at Asuncion it has an elevation of about 70 m. Its sources are in contact with the sources of the Guaporé, a tributary of the Madeira, and those of the Tapajos.

The upper Parana is, in distinct contrast to the Paraguay, a mountain stream arising in the Serra da Mar and the southward extension of the San Francisco plateau. The Rio Grande de Minas, one of its largest tributaries, has at Porta da Rifano an elevation of 590 m. The upper Parana is separated from the lower Parana by the Gran Salto de Guaira, where it leaps over falls of 18 m. to the lowland. Its upper tributaries arise mostly in the coast range near the Atlantic coast and reach the main stream after numerous falls.

A list of the fishes of the Paraguay basin is sufficiently startling on account of the few things peculiar to it, and the many species and genera it has in common with the Amazon, to warrant giving it in detail.

A separate list of species and genera for the Parana, La Plata and Rio Grande do Sul gives us an idea of the relationship of the fauna to that of the Amazon and to that of southeastern Brazil.

There is no room for doubt on the source of the fish fauna of this

region. It came from the north, in small part from the eastern plateau, in greater part from the Amazon valley. The question of the time of the origin of the fauna is of interest. The only observations, as far as I know, directly bearing on this question are those of A. Smith Woodward, 1900, who recorded from the Parana formation fragments of "*Arius*, *Pimelodus*, *Platystomus* and other genera which still live in the freshwaters of South America" and also fragments of characinoids. The formation is a *marine* deposit, near the city of Parana, which he thinks "is truly of late Tertiary age, and may probably be correlated with the Pliocene of the northern hemisphere." As these deposits contain remains of land-mammals, sharks' teeth and fresh-water fishes it is probably an estuary deposit of the former mouth of the Parana river. The present fauna of this stream developed with the stream itself.

List of Fishes Recorded from the Paraguay Basin.

In the following list, "*" indicates that the species is peculiar to the Paraguay basin; "**" that both the genus and species are peculiar; "A" indicates that the species is also found in the Amazon basin; "a" the genus is found in the Amazon basin; and "/" that the species is peculiar to the La Plata. "C" that it is also found in the coast streams of Eastern Brazil and "S" that it is also found in the San Francisco.

It is seen that over 53 per cent. of the total are species that are also found in the Amazon basin; 36 per cent. are peculiar, and over 15 per cent. are common to the Paraguay and eastern Brazil. The proportions common to the Amazon and the Paraguay are not the same for all genera. All of the species of *Sternopygidæ* (7), *Schizodon* (4), *Leporinus* (7) *Serrasalmoninæ* (8), and five out of seven *Mylinæ* found in the Paraguay basin are also found in the Amazon. A comparison of the number of spècies common to the Paraguay and to the Amazon and to the Paraguay and eastern Brazil leaves no doubt as to the origin of the fauna of the Paraguay. It came from the Amazon.

The Parana and La Plata.

The fauna of the Parana and La Plata, as far as known, is quite different from that of the Paraguay. Much of this difference is probably apparent rather than real. The Parana is divisible into two regions—that above the falls with its tributaries belonging to the Brazilian plateau has been mentioned before. Its fauna is very imperfectly known from collections made by Natterer at Irisanga and incidentally described by Kner, and from a collection made by Von Ihering in São Paulo and described by Eigenmann & Norris.

SPECIES OF THE UPPER PARANA, LOWER PARANA, LA PLATA AND RIO GRANDE DO SUL.

	S. E. Brazil.	Upper Parana.	Lower Parana, La Plata.	Rio Grande do Sul.
Exomegas macrostomus (Burmeister).			×	
Galeus vulgaris Müller & Henle.			×	
Raja microps Günther.			×	
R. platana Günther.			×	
Myliobatis aquila (Linnæus).			×	
Potamotrygon brachyurus Günther.			×	
P. hystrix (Müller & Henle).			×	
Bunocephalus iheringii Boulenger.				×
Genidens genidens (Cuvier & Valenciennes).		×	×	×
Netuma upsulonophorus (Eigenmann & Eigenmann).				×
N. barbus (Lacépède.)			×	×
Arius agassizii Eigenmann & Eigenmann.				×

Symphurus plagusia Bloch & Schneider.			×	

The Parana below the falls to Buenos Aires has been made known by Valenciennes, Günther, Perugia, Berg and La Hille.

At this place may also be considered the fauna of that part of Rio Grande do Sul draining eastward. The fauna of this area is more distinct from that of the La Plata than the Paraguayan is from the Amazonian, only about 46 per cent. of its fishes being identical with species occurring in the La Plata. Its affinities are, however, with the La Plata rather than with the coastwise streams north of Rio de Janeiro, only about 30 per cent. of its fauna being identical with that of the northern rivers.

There are known in the region under consideration 170 species which may safely be considered to be less than one-half of the total number of species inhabiting it. Of these, 64 species are also found in the Paraguay, 50, or a little over 29 per cent. are of wide distribution, having been taken in the Amazon. Thirty-four species are common to this region and southeast Brazil. Of these, 15 are included in the 49 recorded from the Amazon, leaving 19 common to the two regions. This number gives us a hint as to the extent to which southeast Brazil has contributed to the La Plata, or the La Plata to the latter.

Of the 31 species recorded from above the falls of the Parana 16 are also found below it.

There is no indication that the fauna of the Rio San Francisco, or the Alta Parana, which is geographically nearer to southeast Brazil, is more like the fauna of the latter region than is the La Plata fauna, for we have:

Number of species in the Upper Parana and Southeastern Brazil	3
Number of species in the Lower Parana and Southeastern Brazil	4
Number of species in the Alta and Baja Parana and Southeastern Brazil	4
Number of species in the Rio Grande do Sul and Southeastern Brazil	8
Number of species in the Rio Grande do Sul, La Plata and Southeastern Brazil	10
Number of species in all four localities	5
	33

VII. The Origin of the Pacific Slope Fauna.

There are four distinct faunas on the Pacific slope of America between Cape Horn and the tropic of Cancer. One of these is of common origin with that on the Atlantic slope, one is autochthonus and the other two are derivative from the Atlantic slope faunas opposed to them.

1. The fauna of southern Chili is essentially like that of Patagonia, and inasmuch as it is largely made up of marine forms entering fresh water, and fresh-water forms entering the ocean, it seems very probable that the species migrated from river to river along the coast from Patagonia to Chili or from Chili to Patagonia.

2. At the other extreme in the Rio Mezquital of the Transition Region and the Yaqui just to the north of it there is a fauna essentially like that of the Rio Grande east of them. As Meek has pointed out, the Yaqui and Mezquital have captured tributaries of the Rio Grande together with the fishes in them, and the migration of Atlantic slope northern forms to the Pacific slope has been a passive one.

Thus, types which in America north of Mexico have not succeeded in reaching the Pacific slope, have, within the Tropics, crossed the divide. *Etheostoma pottsi* is the only representative out of over 50 North American species of *Percidæ* that has crossed the divide and has done it in this way. *Ameiurus dugesi* and *pricei* and *Istlarius balsanus* are the only North American catfishes which have crossed the divide. The Rio Mezquital within the tropics contains *Pantosteus plebeius*, *Hybognathus episcopus*, *Leuciscus nigrescens*, *Notropis ornatus*, all species extending northward

and found in the north only on the Atlantic slope. It also contains *Ameiurus pricei*, one of the three Pacific slope catfishes and *Etheostoma pottsi*, the only Pacific slope Percoid.

3. The third fauna is the Mexican of the Rio de Santiago. This is undoubtedly the relict of an old fauna reënforced by a few immigrants from the north. It is here not a question of the origin of the fauna from an eastern one, but of an autochthonous development that has, on its part, contributed elements to the surrounding rivers. It passively contributed to the Atlantic slope fauna by having one of its small rivers captured by the Rio Panuco.

4. Of more particular interest is the origin of the fauna of western Peru and Ecuador and that of western Central America. Not enough is known of the fauna of the western part of Central America to attempt an explanation of its origin.

To quote the words of Gilbert and Sparks, who considered the marine fishes on opposite sides of Panama (The Fishes of Panama Bay, 205, 1904): "The ichthyological evidence is overwhelmingly in favor of the existence of a former open communication between the two oceans, which must have been closed at a period sufficiently remote from the present to have permitted the specific differentiation of a very large majority of the forms involved." They found that "Of the 82 families of fishes represented at Panama all but 3 (*Cerdalidæ*, *Cirhitidæ* and *Nematestiidæ*) occur also on the Atlantic side of Central America; "while of the 218 genera of our Panama list, no fewer than 170 are common to both oceans." * "Fifty-four out of a total of 374 or 14.4 per cent. of the Pacific coast species are identical with Atlantic coast species."

There seems to me to be just as conclusive evidence that the present fresh-water fauna of the Pacific slope developed *after* the obliteration of the waterway connecting the two oceans, if this waterway occupied the Amazon valley, and that the Atlantic slope streams of the Cordilleras became colonized by their present fauna after the obliteration of this waterway.

The similarity between the Amazonian and Pacific slope faunas of South America is much greater than the similarity between the Atlantic and Pacific slope faunas of North America. This similarity leaves the community of origin of the two faunas unquestioned. Is a continuous coast line between the two slopes necessary to account for the similarity? Such

Range of the most widely distributed genus of characins, Astyanax. (It occurs in Trinidad.)

Range of the characid genus Brycon.

Range of the most widely distributed catfish genus Rhamdia. (In Trinidad.)

Range of Synbranchid eel in America and Asia. One of the two South American genera that have reached Cuba. (In Trinidad.) One species.

To Illustrate the Origin of the Pacific Slope Fauna.

Range of the gymnotid eel, Eigenmannia. Five species.

Range of the characid genus, Hoplias. Three species. (In Trinidad.)

Range of the slender mailed-catfish, Loricaria.

Range of the Cichlid, Æquidens. (In Trinidad.) Probably also in the San Francisco (white).

To Illustrate the Origin of the Pacific Slope Fauna.

Range of the characid genus, Prochilodus.

Range of the characid genus Curimatus. (In Trinidad.)

Range of the minute catfishes of the genus Pimelodella.

Range of the mailed-catfish genus, Plecostomus. (In Trinidad.)

To Illustrate the Origin of the Pacific Slope Fauna.

Known distribution of the Gymnotid genus Sternopygus (three species).

Known distribution of the genera Gasteropelecus and Thoracocharax, two aberrant characins.

Known range of the mailed-catfish genus Hemiancistrus.

Known distribution of the mailed-catfish genus Sturisoma.

To Illustrate the Origin of the Pacific Slope Fauna.

Known range of the Cetopsinæ.

Known range of the characid genus Hemibrycon.[1] (In Trinidad.)

Range of the characid genus Luciocharax.

Known distribution of the characid genus Cheirodon. The species are small, many of them probably unknown. The only tropical genus represented in Chili.

To Illustrate the Origin of the Pacific Slope Fauna.

[1] It is probable that this is a nascent genus arising in different places from different species of the genus *Astyanax* or *Bryconamericus*.

Distribution of the presumably old mountain catfish, Pygidium.

Distribution of the catfish Cyclopium of the high Andes.

Distribution of the mailed-catfish Chætostomus of the Andes. Pacific side of Panama.

Distribution of the Andean characin, Creagrutus.

To Illustrate the Origin of the Pacific Slope Fauna.

a coast line is not needed, because, first, some of the species of the Pacific slope are mountain forms, some of them living on both slopes. If such a genus as *Pygidium* has been able to establish itself from stream to stream along the Andes from Guiana to Patagonia, it needs no continuous waterway to explain its presence on both slopes. The same for more limited reasons applies to *Chætostomus* and *Arges*. Second, a watershed of moderate height is not necessarily a barrier to the migration of fresh-water fishes and several species have evidently succeeded in recent times in crossing the divide in the northwest corner of the continent in one direction or the other, inasmuch as over 27 per cent. of the entire Pacific fauna is also found on the Atlantic, a consensus which is significant and conclusive.

Nearly all the genera found on both slopes, the exceptions to be considered presently, are genera of very wide distribution on the Atlantic slope, reaching the Magdalena or the Isthmus of Panama.

Only four genera are confined to the Pacific slope: *Paracetopsis Lebiasina*, *Pseudochalceus* and *Saccodon*. The other genera represented on the Pacific slope are distributed as follows:

1. *Rhamdia*. Magdalena to the Rio de La Plata and Mexico; Lake Titicaca, San Francisco and Minas Geraes, p. 354.
2. *Pimelodella*. Rio Chagres at Panama to La Plata; Para to Canelos, p. 356.
3. *Paracetopsis*. Canelos to Para; Irisanga, p. 358.
4. *Pygidium*. Andes from Venezuela to Patagonia; French Guiana and southeastern Brazil, central Argentina, p. 359.
5. *Plecostomus*. Magdalena to La Plata and Cordova; San Francisco and southeastern Brazil; Para to Ambyiacu, p. 356.
6. *Hemiancistrus*. Eastern Ecuador to Paraguay, Para and Guiana, p. 357.
7. *Chætostomus*. Eastern and western slopes from Peru to Panama and Venezuela, p. 359.
8. *Loricaria*. Rio Chagres and Magdalena to Para and Buenos Aires; Calderon and Canelos, Xeberos, p. 355.
9. *Sturisoma*.[1] Magdalena to Paraguay; Rio Jurua, Manacapuru; Xeberos, p. 357.
10. *Arges*. Andes of Peru, Ecuador, Colombia and Venezuela.
11. *Cyclopium*. Andes, north of Canelos, p. 359.

[1] This is probably a genus of diverse origin.

12. *Hoplias.* Chagres and Magdalena to Trinidad, La Plata, Para and Huallaga, p. 355.

13. *Curimatus.* Magdalena to Trinidad and La Plata; Para to Huallaga and Canelos, p. 356.

14. *Prochilodus.* Magdalena to the La Plata and Peru, p. 356.

15. *Luciocharax.* Magdalena, p. 358.

16. *Astyanax.* Magdalena to the United States, Trinidad and La Plata and Peru, p. 354.

17. *Hemibrycon.* Peru, Ecuador and Trinidad, p. 358.

18. *Cheirodon.* Magdalena south to San Francisco, La Plata and Chili, p. 358.

19. *Gasteropelecus.*[1] Pacific slope of Panama, Essequibo, Amazons and southeast Brazil, p. 357.

20. *Brycon.* Magdalena to Guatemala and La Plata, San Francisco, Ambyiacu, p. 354.

21. *Creagrutus.* Magdalena to Rio das Velhas. Few species widely separated, an old genus?, p. 359.

22. *Eigenmannia.* Magdalena to Rio San Francisco and La Plata, Para to Pebas, Parana, p. 355.

23. *Sternopygus.* Magdalena to Paraguay and Rio Canelos, San Francisco, p. 357.

24. *Synbranchus.* Magdalena to Rio Motagua, Trinidad, La Plata, p. 354.

25. *Æquidens.* Magdalena to La Plata, p. 355.

All of these show their ability for adaptation and colonization by their wide distribution. The probable route of transit is up the Atrato and down the San Juan, or up the Chagres and down the Pacific side of Panama.

Conspicuous exceptions are the genera *Cheirodon*, *Hemiancistrus* and the *Cetopsinæ*, a group which, until the present, has been considered a single genus. I am entirely at a loss to account for the presence of *Cheirodon* in Chili and no interoceanic channel in the region of the Amazon would help us to account for its presence in Chili or in Patagonia.[2]

[1] Inclusive of the genus *Thoracocharax.*

[2] The *Cetopsinæ* are found on the Atlantic slope throughout the length of the Amazons to the Huallaga in Peru and up the Napo to the mountain streams about Canelos, Ecuador, and are also found directly across the Andes from Canelos in the Guayaquil. The inference is obvious. *Paracetopsis* has succeeded in getting across the Andes of Ecuador at a sufficiently long time ago to enable the Guayaquil form to become generically and specifically distinct. *Hemiancistrus* has a similar distribution, being also found on the western slope of Panama.

Of the genera peculiar to the western slope *Protisius* and *Gastropterus* are of marine origin not related to Atlantic slope forms. They are found at high altitudes and are remnants of early colonists from the sea. *Lebiasina* is a genus of *Characidæ* very closely related to *Piabucina* of wide distribution on the Atlantic slope. *Saccodon* is related to *Paradon*, distributed from the La Plata to Colombia and to *Hemiodus* from the Orinoco to the San Francisco, the Peruvian Amazon and the upper courses of the Paraguay. From one or the other it is probably an offshoot, sufficiently remote in time to be generically different. All of the genera are very probably among the oldest on the continent.

It is seen that the present distribution of the fresh-water fishes does not require an interoceanic waterway for its explanation. Does the present distribution of fresh-water fishes offer any objection to such an interoceanic connection in recent times? Two or three things are opposed to this supposition. One is the paucity of the Pacific fauna in general, and the second the absence of many Atlantic slope families, especially the *Lepidosirenidæ*, *Aspredinidæ*, *Hypophthalmidæ*, *Callichthyidæ*, *Electrophoridæ*, *Osteoglossidæ*, *Arapamidæ* and many dominant Atlantic slope genera, all of them lowland forms, and the third the absence of all tropical American forms, except *Pygidium* from Lake Titicaca.

If the reigning fauna had been present on the eastern slopes of the Andes even in outline at a time of the interoceanic canal, a very much larger per cent. of the Atlantic slope forms ought to be found on the Pacific slope, unless the Pacific slope streams were uninhabitable, or, unless the fauna became extinct, after the separation of the oceans and the streams were repopulated by new emigrants from the east.

The meagreness of the Pacific slope fauna is probably in great part due to the small rivers and precarious water supply. It can scarcely be supposed that a fauna became extinct to be replaced by a similar one. It is quite certain that its present fauna has been derived from forms whose wide distribution shows them to be especially fit to cross existing barriers and which were probably the very first to reach the Atlantic slope of the Andes. All of them are old genera, among the oldest on the continent.

If the present fauna had been in existence along the Andes at the time Lake Titicaca was much lower, it ought to have received a fair sprinkling at least of the fresh-water fauna, but it contains little but marine types.

All of these considerations lead me to conclude that the present fauna

migrated to the Pacific slope subsequent to the formation of the Andes and after the obliteration of the interoceanic sea, if such existed in the place supposed, and long after the colonization of the coast streams of Minas, etc.

If the supposition be established, that few, if any, ancient Atlantic slope forms reached the Andes in time to cross the divide by going from stream to stream along oceanic channels, it indicates very strongly that the fresh-water species were unable to bridge the gap between the ancient land masses, Archiplata and Archiguiana and the Andes. Such inability to cross even moderate seas would be strong evidence that they could not have crossed the Atlantic, and that there must have been continuous land, or land at frequent intervals or better still, a land wave carrying the families common to Africa and South America from a center to both these continents.

The fact that the Pacific slope fauna is generically all but identical with the Atlantic slope fauna, and that the latter is generically different from the African fauna, makes it certain that the Pacific slope fauna was derived from the Atlantic slope fauna long after Guiana was separated from Africa.

VIII. The Necessity and Evidence of a Former Land Connection Between Africa and South America.

Not a single species of South American fresh-water fishes is found in North America, nor do any North American species reach South America. Two prominent South American families, the *Characidæ* and *Cichlidæ* have representatives as far north as the Rio Grande basin, and one of these has succeeded in crossing over into Cuba, evidently from Yucatan; on the other hand, several members of the North American fauna have representatives as far south as the Isthmus of Tehuantepec. The North American fauna is entirely distinct from the tropical American fauna.

But four genera of fresh-water fishes of South America north of Patagonia are found in any other continent than North America. These are *Synbranchus*, *Agonostomus*, *Cotylopus* and *Fundulus*. The first is found also in brackish water, the second belongs to the marine family *Mugilidæ* and the other to the *Pœciliidæ*. *Synbranchus* (map, p. 354) is found in India, *Agonostomus* in Middle America, West Indies, northern South America and New Zealand, Australia, Celebes, Mauritius and Comoro Islands. There is no reason why *Agonostomus* may not have been independently evolved in the South Sea and in America from marine mugilids.

Cotylopus is found in Central America and Reunion Island, Africa, *Fundulus* in America and Europe.

It is possible that *Pimelodus* is found in Africa, and *Pseudauchenipterus* in Madagascar. Both are found in South America.

Tropical Africa and Tropical South America have two groups of families

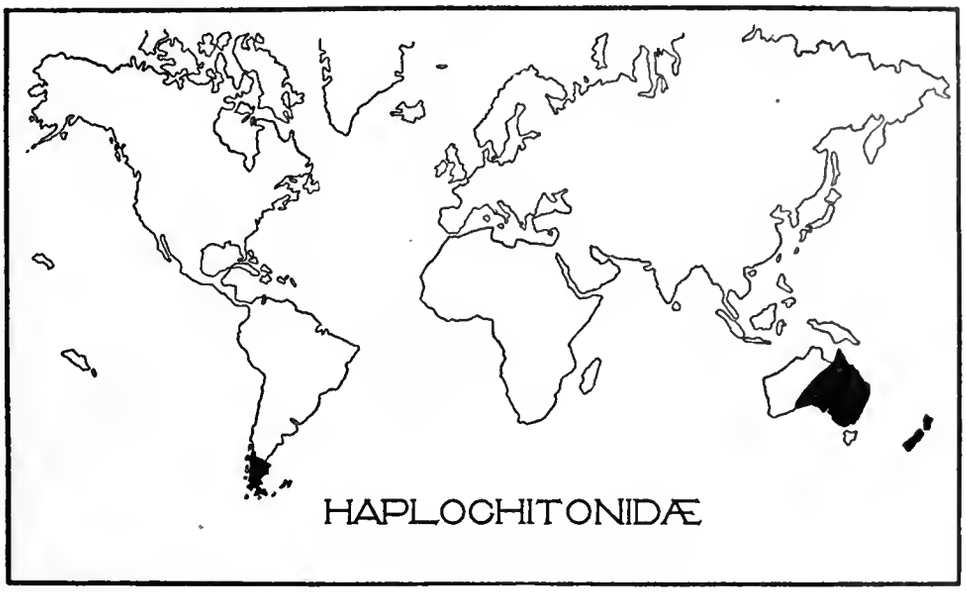
Range of the Petromyzontidæ.

Range of the Galaxiidæ.

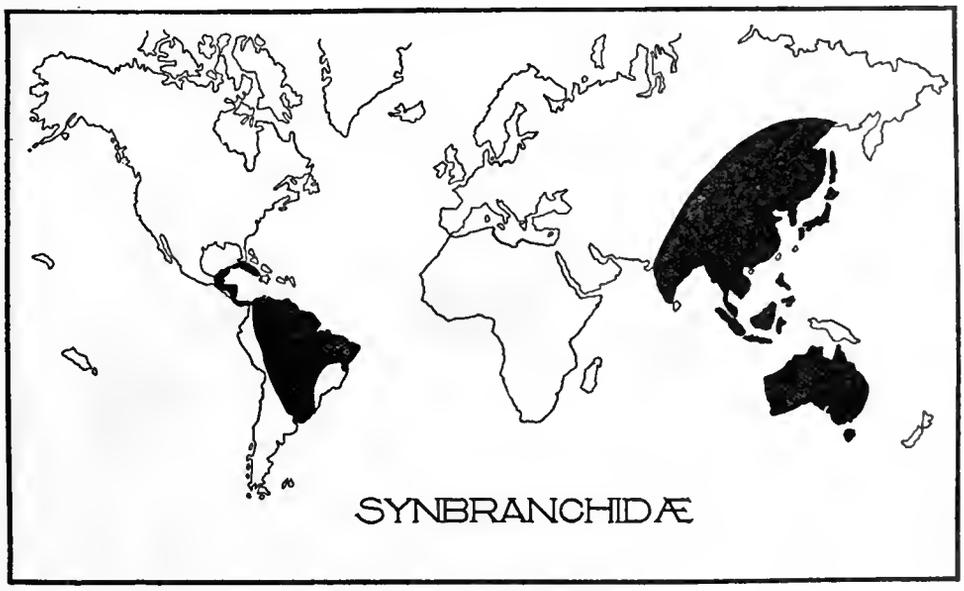
To Illustrate the Origin of the South American Fresh-water Fish-fauna.

in common. The first group comprises the *Serranidæ*, *Sciænidæ*, *Mugilidæ* and *Tetraodontidæ*.

These are all marine families, some of which have also developed fresh-water forms in Europe and North America as well as in South America. The fresh-water forms of South America and Africa are local adaptations



Range of the Haplochitonidæ.



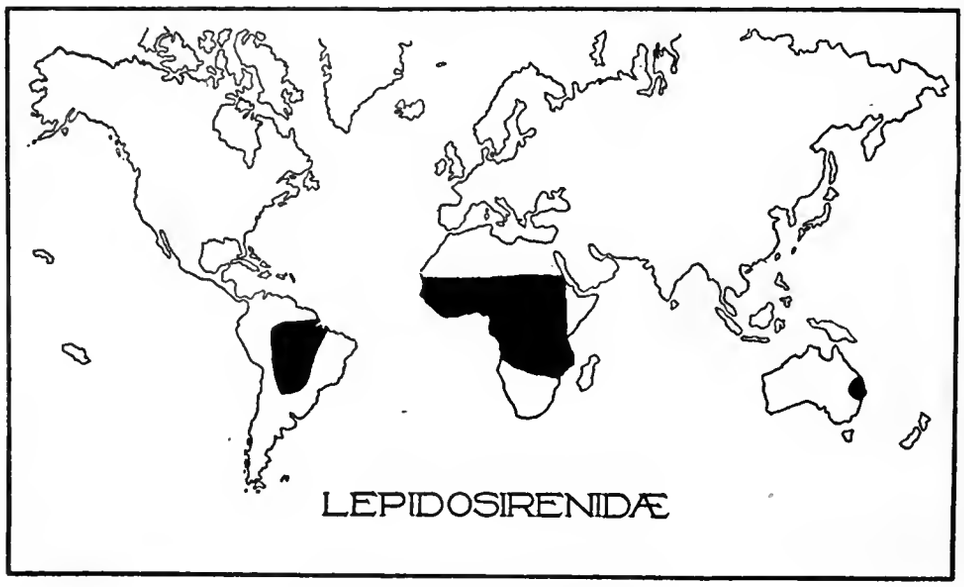
Range of the Synbranchidæ.

To Illustrate the Origin of the South American Fresh-water Fish-fauna.

of marine families that require no change in the present conditions to account for their origin.

The second group comprises the *Lepidosirenidæ*, *Osteoglossidæ*, *Siluridæ*, *Characidæ*, *Pœciliidæ* and *Cichlidæ*.

Of these, the *Lepidosirenidæ* are relicts of a formerly widely distributed group, and it requires no land connection satisfactorily to account for

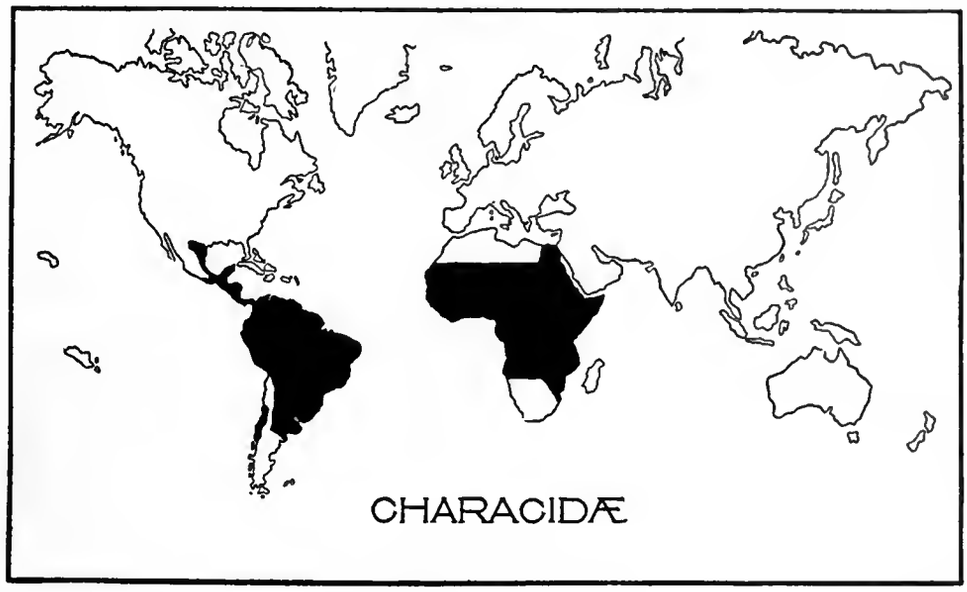


Range of the Lepidosirenidæ.

Range of the Osteoglossidæ.

To Illustrate the Origin of the South American Fresh-water Fish-fauna.

their presence in Africa and South America. The *Pœciliidæ* live indifferently in marine, brackish water or fresh water. They reach their maximum development in the fresh waters of Mexico, the West Indies and Central America. The marine species are found along the shores—not at sea—and there is, therefore, at present, no known means of getting



Range of the Characidæ.

Range of the Pœciliidæ.

To Illustrate the Origin of the South American Fresh-water Fish-fauna.

them from the American to the African shore. Nevertheless, *Fundulus* is found on both sides of the Atlantic, and there must have been an intermigration much more recent than the youngest possible land connection between Africa and South America, or else there has been a very long persistence of this genus. A land connection, while not absolutely required for this family, would be very convenient.

The *Siluridæ* are in part marine. All of the South American forms of *Siluridæ* can be derived from the marine *Tachisurinæ* and the same is probably true of the African members of the family. Furthermore, the catfishes are found in North America, Europe and Asia, and have been recorded in North America also from the Tertiary. A land connection between Africa and South America is, therefore, not absolutely required to account for their presence in both continents, though, as in the case of the *Pœciliidæ* such a connection would be very convenient.

The *Cichlidæ* and *Characidæ* are abundant in tropical America and in Africa, a few species of *Cichlidæ* being also found in India. There is no known means by which these two forms could have crossed the existing gap between Africa and South America. There has been no exchange of species in recent times, for there is no species or genus common to the

MAP TO ILLUSTRATE THE MIGRATIONS OF SOUTH AMERICAN FRESH-WATER FISHES.

two continents. The South American and African elements of these two families must have been derived from some intermediate land-mass or must have gone from one continent to the other over a land bridge. That this connection, whatever it was, must have been obliterated before the Tertiary, is evidenced by the facts that the Tertiary deposits of Taubaté and Parana show existing genera and that there are many South American types, as the *Gymnotidæ*, *Electrophoridæ*, *Bunocephalidæ*, *Loricariidæ*, *Argiidæ*, *Pygidiidæ*, *Callichthyidæ*, *Hypophthalmidæ*, et al., not found in Africa, that have all arisen in South America from the *Characidæ* and *Siluridæ* since the separation of the two continents.

Similarly, other families found in Africa and not in South America have either arisen in Africa since that time or have immigrated from the East.

A land connection, whether a land bridge, intermediate continent or land wave between the two continents, is imperative. This land connection must have existed before the origin of existing genera and before many of the existing families.

On the other hand, Boulenger (Les Poissons au Bassin du Congo, VIII) explains the similarity of the South American and African faunas as "without doubt the result of the persistence in these two parts of the world of types more generally distributed at a very remote epoch which have disappeared in other regions, as palæontology shows us, among others, to be the case with the Dipneustes, which belong to this category.

"Nothing is gained by explaining these similarities by interpolating a hypothetical continental continuity which could not have existed except at a time previous to the development of the groups of teleostean fishes which Africa and South America possess in common."

IX. The Points of Origin and Lines of Dispersion of Tropical American Fresh-water Fishes.

The study of the distribution of fresh-water fishes has led to these general conclusions.[1]

The origin and distribution of the fresh-water fishes of tropical South America has come about as follows:

[1] It has been sufficiently emphasized in the first section of this report that the fauna of "Archiplata" or Patagonia is not related to or contains but a few intrusives from the Tropical American Fauna.

In the earliest Tertiary tropical America consisted of two land areas, Archiguiana and Archamazona, separated by the lower valley of the Amazon which was still submerged.

There was a land mass between Africa and South America — possibly in contact with Guiana in South America and some point in tropical Africa. This land mass was inhabited, among others, by *Lepidosirenidæ*, *Pœciliidæ*, *Characidæ*, *Cichlidæ* and *Siluridæ*. This land mass sank beneath the surface of the ocean, forcing the fauna in two directions, towards Africa and towards South America, exterminating all types not moved to the east or the west. From these two rudiments have developed the present diverse faunas of Africa and South America, each reënforced by intrusives from the ocean and by autochthonous development, by immigrants from Africa, also neighboring land areas. The one fauna cannot be said to have been derived directly from the other.

The connection between Africa and South America existed before the origin of present genera and even before the origin of some of the present subfamilies and families, some time before the earlier Tertiary. There has never been any exchange between Africa and South America since that time. There must have been an intimate connection between these two continents, for there is no evidence, such as identical species or genera on the two coasts, to indicate an occasional or accidental exchange of types across the Atlantic since the formation of existing genera, therefore, such an interchange across the ocean probably never took place. The East Brazilian land mass south of the Amazon (Archamazona) must have become stocked from the western end of Helenis (Archiguiana) very early, for it contains many genera peculiar to the region, indicating a long separation, and Tertiary fresh-water deposits in this area contain existing genera of fresh-water fishes. The Pacific slope fauna is a more recent acquisition from the east.

When, later, the Cordilleras arose out of the ocean at a distance from Archiguiana and Archamazona too great to be traversed by colonists from them, their developing streams and arms of the sea, connected with brackish, and later fresh-water lakes, all became populated with marine types from the surrounding sea. In the north where they came in competition with immigrants from Archiguiana, most of them were exterminated with the continued elevation of the land. On the south which was not or was not so early reached by immigrants, *Orestias*, *Gastropterus*,

and *Protistius* remain in the high Cordilleras of southern Peru as relicts of these marine species. Later, these mountain streams, especially those of Ecuador and Colombia, became populated by stragglers or accidental visitors from the land areas to the east. These in their turn, with the elevation of the Andes, became modified and gave rise to the genera now peculiar to both slopes of the high Andes, *Pygidium*, *Eremophilus*, *Chætostomus*, *Arges*, *Cyclopium*, *Astroblepus*, etc.

With the further elevation of the Cordilleras into a continuous barrier and the formation of the Orinoco, Amazon and La Plata valleys through elevation and the debris brought from the land masses, and the development of the enormous fresh-water system occupying these valleys, this system, particularly the Amazon, became colonized from the older land areas and became the center of unparalleled adaptive radiation and a new center for distribution, which it has remained to the present time.[1] The comparatively few types inhabiting the old eastern land masses found themselves in possession of a continent and diverged along every conceivable direction, the characins alone giving rise to over 500 species and over 100 genera.

From the Amazon species moved in all directions till they met barriers of one sort or another. The Pacific slope fauna is derived to a very large extent from this latter divergent migration over the isthmus of Panama and through the Atrato valley between the western and coast Cordilleras of Colombia. Others possibly crossed over the Andes east of Guayaquil before the Andes reached their present height. The Pacific slope fauna is less different from the Amazon fauna than that of the coastwise streams of Minas, if the number of peculiar genera is used as a measure of difference. Amazonian types moved south till climate and barriers checked them south of Buenos Aires. They migrated northward till they came in competition with emigrants from the north in the lowlands of Mexico.

The origin of the fauna of the plateau of Mexico is a separate subject. This fauna is in part of marine origin and antedates, in a large measure, the mongrel fauna of the Mexican lowlands.

[1] Amazonian species form six or seven per cent. of the fauna of the Motagua, five of the Pacific slope fauna, over 30 per cent. of the Magdalena fauna, over 42 per cent. of the Trinidad fauna, over 50 per cent. of the fauna of the Guianas, over 40 per cent. of that of the San Francisco, about 30 per cent. of the fauna of the coastwise streams east of the San Francisco, and over 50 per cent. of that of the Paraguay.

Evidence for these conclusions has been given in detail in the foregoing pages. The basis for the entire discussion is a list of the species giving their geographical distribution. Such a list has been prepared and follows this discussion.

The points of strategic importance for ichthyic chorology in South America are, therefore, (*a*) western Colombia and Panama; (*b*) Guayaquil and Peru to the Amazon, across the Andes; (*c*) the tableland of Guiana, Archiguiana; (*d*) the Rio San Francisco, with the Rio Parahyba and the headwaters of the Tieté and Rio Grande, in Archamazona, and (*e*) the area between the Rio Negro and the La Plata.

Note on Lake Titicaca and its Fauna.

In conversation with Prof. G. Steinmann the latter called attention to his views concerning Lake Titicaca, which he had the kindness to write out for me.

"The region at present covered by Lake Titicaca was formerly, as late as late Tertiary times, a normally drained area. Its drainage was southeast toward the Amazon. It was not till the Glacial epoch that the glaciers of the high Andes pushed their moraines into the drainage valley and formed the lake. It is, therefore, a glacial-dam lake which did not retain its Amazonian drainage, but flowed over the low watershed southeast toward the undrained high plateau of Bolivia. There is no evidence that the lake was formerly connected with the Pacific. Not only are there no marine formations in the inter-Andean high plateaus of northern Bolivia and southern Peru belonging to the Diluvial time, but also those of Tertiary times are lacking. For this reason also the fauna of Titicaca cannot be explained as a relict, but must have arisen from the ocean by migration in a roundabout way through former rivers and lakes."

In my account of Lake Titicaca it was assumed that the origin of the lake from an arm of the sea was without question, and an attempt was made to explain its fauna on that basis. It was assumed that the genus Orestias gave rise to numerous species, some of which succeeded in crossing the divide into neighboring rivers. The explanation of Steinmann would obviate the difficulty of originating numerous species from one type in a restricted unit environment. General observation everywhere gives evidence that segregated individuals of a given species tend to diverge from the central type, not that a species mutates into a large or

small number of species in a restricted locality. It seems as reasonable to assume that Orestias migrated from the ocean into all streams when the Andes were low, became different in these segregated environments, and filtered from them into Lake Titicaca, as to assume that it became landlocked in an arm of the sea when that was cut off by elevation, gave rise to numerous species in the one locality, and migrated from the lake to the headwaters of neighboring streams.

The Fauna of the Rio Rebeiro.

During the years 1907 and 1908 a series of papers on the fishes of the Rebeiro by Rebeira and the Cubatao by Steindachner have shown that these isolated rivers have a fauna, nearly half of which is peculiar. They are streams in the northern part of the state Sta Catharina emptying into the Atlantic. The material came too late to incorporate in the proper table without entirely resetting it. A list of the fishes from these rivers is, therefore, given here. This peculiar fauna, situated between Rio Grande do Sul of the La Plata province and the Parahyba of eastern Brazil, demonstrates very well that the streams emptying into the Atlantic do not form a highway for ready migration from the North or South.

AKODON

EXPLANATION OF PLATE XII.

AKODON, six species, and PHYLLOTIS MICROPUS.

PAGE

Fig. 1–1*a*. AKODON XANTHORHINUS: Upper and lower teeth, greatly worn, ♂ ad., × $\frac{4}{1}$. Skull figured on Plate XI, Fig. 1–1*b*. No. 13, Colburn Collection. 71

Fig. 2–2*a*. AKODON XANTHORHINUS: Upper and lower teeth, of a young specimen with unworn teeth, for comparison with Fig. 1–1*a*. Punta Arenas, Patagonia. No. 7, Colburn Collection.

Fig. 3–3*a*. AKODON CANESCENS: Upper and lower teeth, greatly worn, ♂ ad., × $\frac{4}{1}$. Skull figured on Plate XI, Fig. 2–2*b* 73

Fig. 4–4*a*. AKODON CANESCENS: Upper and lower teeth, ♂ juv., with unworn teeth, for comparison with Fig. 3–3*a*. Mouth of Rio Gallegos, Patagonia. U. S. Nat. Mus. No. 92,192.

Fig. 5–5*a*. AKODON CALIGINOSUS: Upper and lower teeth, greatly worn, ♀ ad., × $\frac{4}{1}$. Skull figured on Plate XI, Fig. 3–3*b*.

Fig. 6–6*a*. AKODON CALIGINOSUS: Upper and lower teeth, unworn, ♀ juv., for comparison with Fig. 5–5*a*. Inca Mines, Peru. Am. Mus. No. 16,055.

Fig. 7–7*a*. AKODON PULCHERRIMUS: Upper and lower teeth, greatly worn, ♂ ad., × $\frac{4}{1}$. Skull figured on Plate XI, Fig. 4–4*b*.

Fig. 8–8*a*. AKODON PULCHERRIMUS: Upper and lower teeth, unworn, for comparison with Fig. 7–7*a*, ♂ juv., × $\frac{4}{1}$. Inca Mines, Peru. Am. Mus. No. 16,510.

Fig. 9–9*a*. AKODON SUFFUSUS: Upper and lower teeth, greatly worn, ♂ ad., × $\frac{4}{1}$. Skull figured on Plate XI, Fig. 5–5*b*. . . . 76

Fig. 10–10*a*. AKODON SUFFUSUS: Upper and lower teeth, very slightly worn, for comparison with Fig. 9–9*a*, ♂ juv., × $\frac{4}{1}$. Upper Rio Chico, Patagonia. U. S. Nat. Mus. No. 84,322.

Fig. 11–11*a*. AKODON VESTITUS: Upper and lower teeth, greatly worn, ♀ ad., × $\frac{4}{1}$. Skull figured on Plate XI, Fig. 6–6*b* . . . 78

Fig. 12–12*a*. AKODON VESTITUS: Upper and lower teeth, slightly worn, ♀ juv., for comparison with Fig. 11–11*a*, × $\frac{4}{1}$. Upper Rio Chico, Cordilleras, Patagonia. U. S. Nat. Mus. No. 84,235.

Fig. 13–13*d*. PHYLLOTIS MICROPUS: Skull (× $\frac{2}{1}$) and upper and lower teeth (× $\frac{4}{1}$), ♂ ad., with the teeth greatly worn. Upper Rio Chico, Cordilleras, Patagonia. U. S. Nat. Mus. No. 84,338. . 60
